
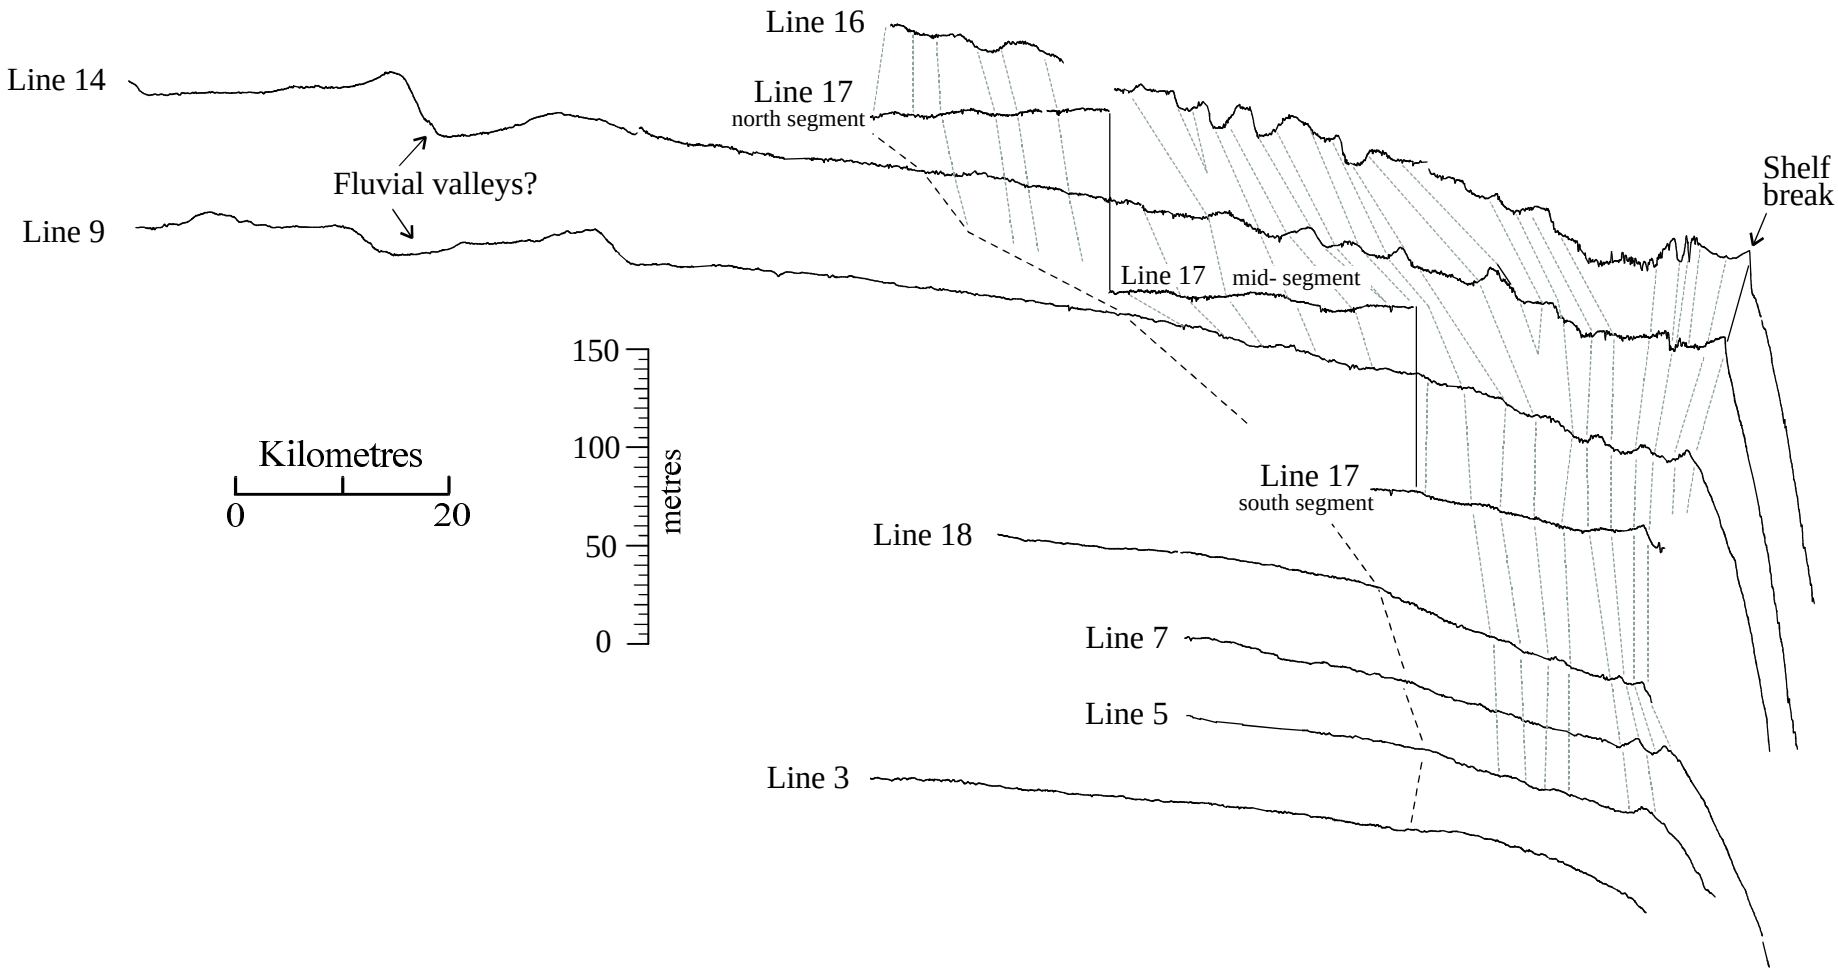

Figure 29. Bathymetric profiles across the moraine field showing their character and correlation, (with the aid of the bathymetric chart). The ridges to the south are lower relief, with the exception of the shelf-break moraine. Nn the northern three profiles this moraine has a prograding structure interpreted as a “till delta“ (see also Fig. 27). The heavy dashed line separates the till/moranic field from a much more subdued, nearly planar topography in the shallow areas. In the south this is marked by an inflection in the profile, best developed on lines 3, 5 and 18. Line 17 has been divided into segments as it intersects the northern lines.
