LEGEND

Note: This legend is common to National Geochemical Reconnaissance Map 1-3-NTS, Open File 413, Map 1-5-NTS, Open File 414 and Map 11-NTS, Open File 415

MELVILLE

[illegible] Gabbro, meta-gabbro and diabase dykes [GGGB]

[illegible] Granite, quartz monzonite and granodiorite (Baffin Lake granite) [GMMT]

ANGUNIA

[illegible] Granite, quartz monzonite and granodiorite [GPMS]

[illegible] Lithic greywacke to subgreywacke [GGGU]

[illegible] Conglomerate [GCGM]

[illegible] Arkose to subgreywacke [AAAS]

[illegible] Lahar, quartz feldspar tuff and tuff breccia [GCCT]

[illegible] Metapelitic, psammitic, calc-silicate bands derived from [illegible] [GMMA]

[illegible] Dendroid [illegible], [illegible] and [illegible] [GMMG]

[illegible] Dolomite, limestone and minor argillite, phyllite [GMMS]

[illegible] Gabbro sills [GGGM]

[illegible] Argillite, phyllite, greywacke, some minor dolomite [GMMA]

[illegible] Quartzite, orthoquartzite [GMQT]

[illegible] Greywacke-conglomerate, greywacke, orthoquartzite [GCGW]

[illegible] Mafic-gabbro dykes [MMGM]

[illegible] Quartz monzonite, granodiorite and granite; massive to foliated [GLPM]

[illegible] Diorite and gabbro [GMMT]

[illegible] Grey biotite granodiorite gneiss [GGGNG]

[illegible] Ferropodzolic, minor paraconitic [PMMG]

[illegible] Amphibolite, amphibolite gneiss [GMMAG]

[illegible] Greywacke, greywacke-conglomerate, argillite, phyllite, minor tuff [GMMG]

[illegible] Meta-ultramafic rocks [MMUU]

Drift covered area.....

Geological contact.....

Fault.....

Limits of geological mapping.....

Eskers (direction of flow known).....

Mineral occurrence.....

Legend modified and geology derived for the geochemical map by R.G. Garrett from maps 24-1070, 3-1972 and 4-1972 and G.S.C. Paper 74-54 by H.C. Gade

Geological cartography by the Geological Survey of Canada

Base-map at the same scale published by the Mapping and Charting Establishment, M.C.E., 1963

Mean magnetic declination 1977, 34°25.1'E decreasing 4.8' annually. Roadings vary from 34°16.4' in the SE corner to 34°32.2' in the NW corner of the map area

Elevation in feet above mean sea-level

Geochemical Symbol and Data Presentation

The concentration of an element at a sample site is graphically represented as one of 15 symbols. If a sample was collected but there is no data available a dot is plotted. The symbols are symmetrically arranged so that they first intercept the eye as a function of increasing data value when scanning clockwise from 12 o'clock. The two small crosses at the low end of the scale are used to resemble denote concentrations below the analytical detection limit, or, in the data group containing the detection limit. The data are grouped on a semi-logarithmic scale, i.e. 1,2,5,10,20,50,100 etc. Five decades can be spanned and this arbitrary division of the data allows comparison of adjoining Canada wide series of maps constituting the National Geochemical Reconnaissance.

The choice of symbols and the data groups they represent for any specific element is based on the histogram and cumulative frequency plot for the total survey data from one, or more contiguous, open file sheets covered in one field season. The histogram is used to select the data groups and to plot the symbols. This group usually includes the median of the data as defined by the 0.5 (50%) point on the cumulative frequency plot. Some, or all, of the remaining 14 symbols are chosen so as to achieve an appropriate graphical impact. An example of all 15 symbols is given below.

The data groups, which are based on the total survey data distributions, are unaffected by the availability of ever increasing levels of knowledge in bedrock and surficial geology, and other environmental factors. Therefore, the raw data symbol maps are only intended to assist the rapid inspection of the data for gross regional features. To fulfill the needs of a more specific and thorough interpretation, the raw data should be used in conjunction with the sample location map provided in the data listings and any other knowledge available. To assist in the appraisal and modification of the data in terms of the symbol map bedrock geology, a table of summary statistics and proposed threshold values for drainage samples dominantly derived from each mapped bedrock unit, or broad lithologic unit, again based on the total survey data from one, or more contiguous, open file sheets, can be used along, or in conjunction, with the sample location map and data listings to indicate above threshold samples where they occur on the map. In many instances, the table will also illustrate, more clearly than the map, the dependence of mean geochemical levels on bedrock type. It may often be also observed that the data for a specific element from a given lithologic unit exhibits multiple data for individual map or lithologic units appears to approximate a normal distribution. The proposed thresholds presented are believed to be useful in interpreting the data from a stream sediment reconnaissance. Locations of samples with concentrations in excess of the threshold for the rock unit they appear in should be investigated. Depending on the nature of the mineralization, anomalies can be due to a wide range of geological and environmental factors, but one of these could be the presence of abnormal concentrations of the element in a form of interest to the mineral exploration industry.

To comprehensively study an area, all available geological, environmental and recorded data should be utilized. The data separation by bedrock type can often be improved by constructing new data subsets and deriving local threshold levels based on the most detailed and up-to-date knowledge available.

The data listings, in addition to the sample location map, provide a means to estimate the reliability of the geochemical maps. On the basis of duplicate sampling 51 of all lakes sampled it can be stated that there is a 95% chance that if any lake is resampled and identical methods of sample preparation and analysis are used the new value will lie between 3 × RF and 0 × RF where R is the original value obtained. This factor takes into account variability due to both heterogeneity of the centre-lake bottom sediments and sample preparation and analytical causes.
