
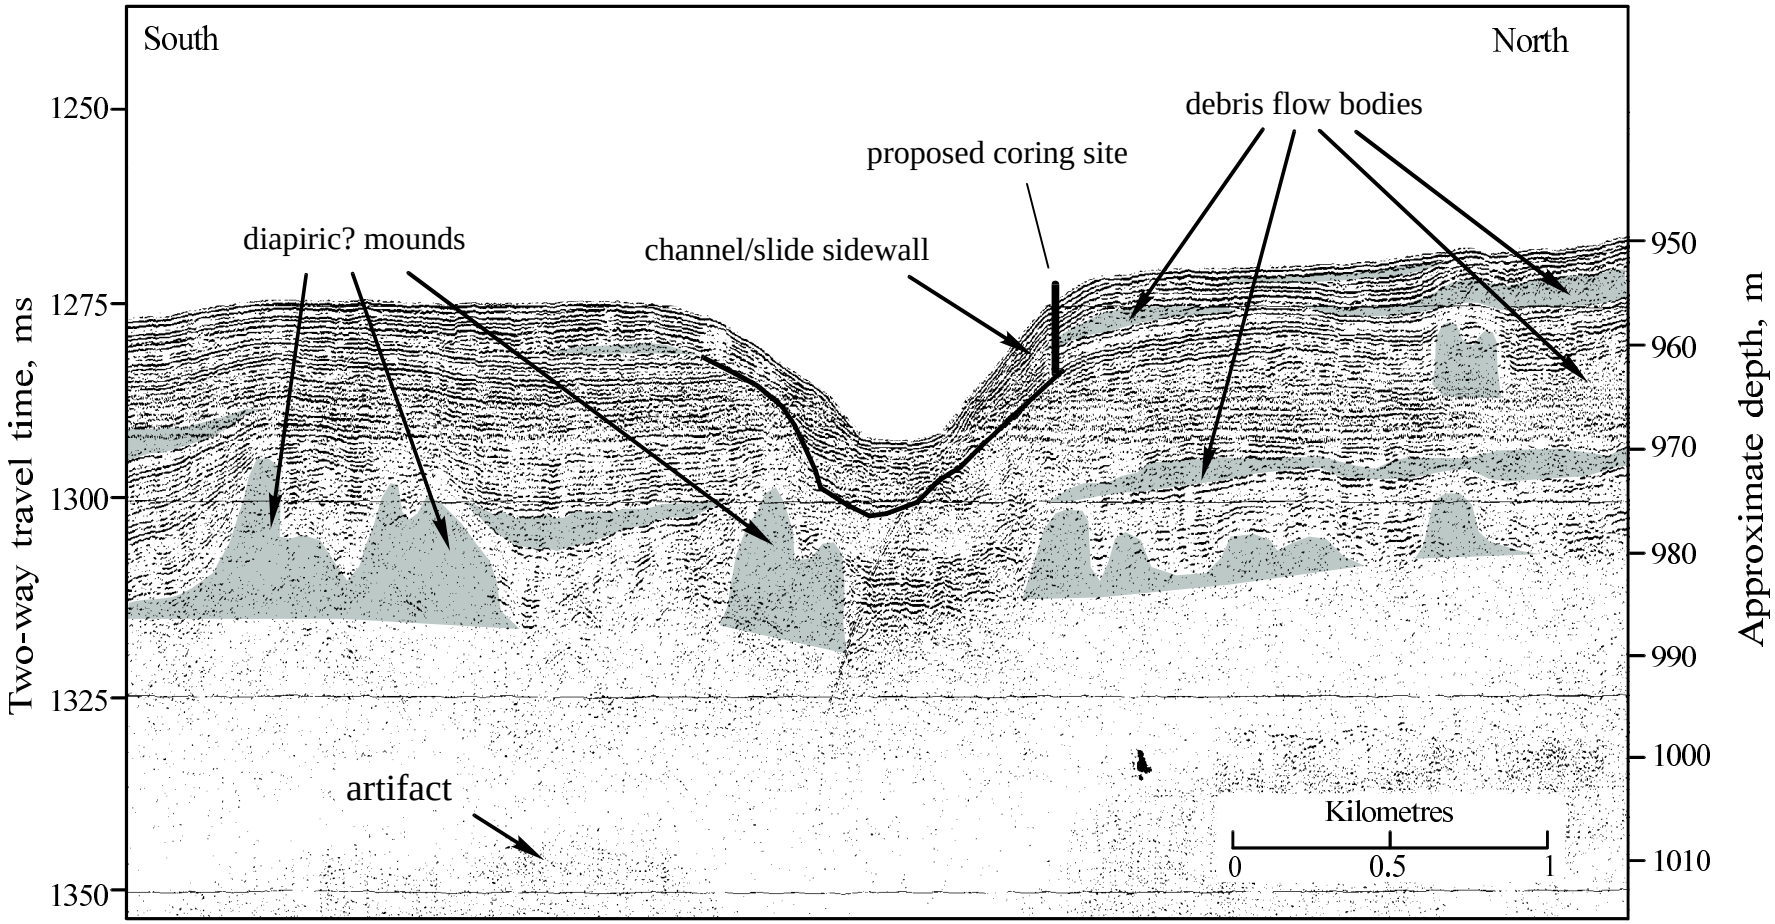

Figure 22. Huntec deep towed boomer profile from lower slope (Line 8, time 2335 to 0009) showing an erosional scarp of a channel or small slide cut in laminated sediments with an overlying draping unit. Isolated, lensoid debris flow bodies at three horizons are identified. Local unconformities are present within the layered sequences. A core at the selected site has the potential for better sedimentologic and chronologic characterization. The mounded (ridge?) features with partially draping laminites might result frommuddiapiric action.
