

Normal curves showing the thickness (average), number, and correlation of the annual clay layers formed during part of the ice retreat northeast of The Pas, Manitoba. Thicknesses are represented one-half actual size. The numbers opposite an arrow head indicate the number of measured series of varves employed in constructing the parts of the curves indicated by the arrows, thus : 5 : 181-182-182-184-185 means that five measured series were employed, two of which were measured at locality 182; and 2 : 188-189 (190) means that, besides employing two measured series from localities 188 and 189 respectively, a measured series from locality 190 was employed to help determine the number of varves but not for any other purpose.
