Department of Mines and Technical Surveys.

No correction has been made for regional variation.

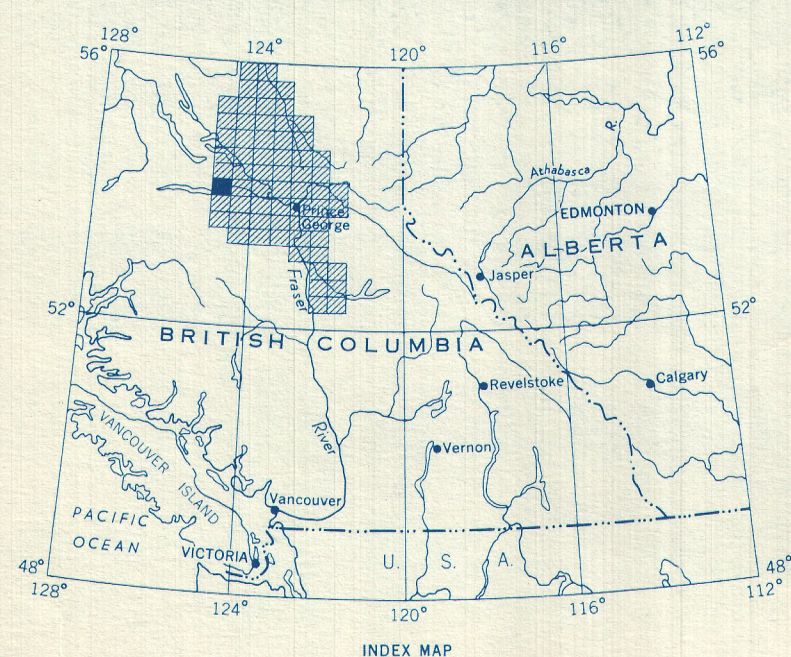

The planimetry was obtained from topograph-
ical sheets published by the Department of Mines and
Technical Surveys and the British Columbia Surveys
and Mapping Branch, Department of Lands and Forests.

The magnetic data on this map were compiled from information recorded along the flight lines shown. The anomalies expressed by the magnetic contours are dependent on the variable magnetic intensities of the underlying rocks, and may be due to conditions near, or at unknown depths below the surface. High magnetic anomalies normally indicate the presence of basic rocks, such as diabase, gabbro, or serpentinite, which have a relatively high iron content, but in special instances may be due, or partly due, to concentrations of magnetic ore minerals. By means of the magnetic anomalies, various rock bodies or structural features, such as faults or folds, may be traced by the geologist into, or across, areas of few, or no outcrops. In many instances, however, no interpretation of particular anomalies may be possible without further geological information.
