CANADIAN SIESMOGRAPH OPERATIONS — 1986

Abstract

At the end of 1986 the Division of Seismology and Geomagnetism of the Geological Survey of Canada, Department of Energy, Mines and Resources, operated or contracted the operation of 15 standard seismograph stations, 43 regional stations, 2 telemetered networks, based in Ottawa and near Victoria, a medium-aperture array at Yellowknife, two strong-motion seismograph networks on the east and west coasts and several special or temporary seismographs. This report gives the characteristics of the various systems and describes the format and availability of the recorded data.

1. INTRODUCTION

This report is published annually as part of the Seismological Series of the Geological Survey of Canada. It contains summary information on the seismograph installations operated by, for, or in cooperation with the Geophysics Division, Geological Survey of Canada, Department of Energy, Mines and Resources. This information includes a brief description of the various types of seismograph installations, the data produced, the data processing procedures and facilities and the availability of station data and records. Summary information on instrumental changes in the network and calibration curves for the seismograph stations are included in the latter pages of the report.

2. CANADIAN SEISMOGRAPH NETWORK

2.1 General

The Canadian Seismograph Network (CSN) is composed of various types of seismograph installations, which are briefly described in the following sections. At the end of 1986, these installations included 15 standard stations (minimum of six daily records), 43 regional stations (minimum of one daily record), a 21-station, short-period, vertical-component network telemetered into Ottawa, a similar 18-station network telemetered into Sidney, a short and long-period vertical seismograph array situated at Yellowknife, two strong-motion seismograph networks and several special or temporary installations.

2.2 Standard Stations

A standard station consists of three orthogonal short-period seismographs and three orthogonal long-period seismographs, each producing a photographic record or a visual record on a Helicorder. Table 1 lists stations, locations and operators in alphabetic order by station code (see also Figure 1). The short-period seismometers used in most standard stations are Willmores with a nominal period of one second. The seismometer signal, after passing through the attenuator, which has resistors arranged in a TEE-pad formation, is fed into a Tinsley galvanometer having a nominal period of one-quarter second. The Montréal station has a standard short-period Benioff system. The three long-period Columbia seismometers used in all standard stations have their free period nominally set to 15 seconds. The same type of attenuator TEE-pad formation used in the short-period seismographs is also used in the long period seismographs. The long-period Lehner-Griffith galvanometers have a nominal period of 90 seconds.

Accurate timing is provided by a Sprengnether TS-100 chronometer or a Geological Survey of Canada digital chronometer rated against the national time service CHU or WWV. For stations equipped with Sprengnether chronometers, a calibration pulse, corresponding in initial direction to a compression of the ground, is applied to the three long-period seismometers at 00^h and 12^h U.T. (Lombardo *et al.* 1977, p. 17). For stations with digital chronometers (FRB, SCH, INK, ALE, MBC, YKC), the calibration pulse is applied only at 00^h U.T. At station INK only, it corresponds to an initial dilatation of the ground, producing an initial downward response on these seismograms instead of upward, as at the other stations.

A Sprengnether three-component photographic recorder is used for both short and long-period seismographs. The short-period recorder drum rotation rate is set to 60 mm per minute, and the long-period rate at 15 mm per minute.

Calibration curves for all standard stations and any instrumental changes made during the year are included in Section 4 in alphabetical order by station code.

2.3 Regional Stations

Regional seismograph stations are used in seismically active areas of Canada to supplement the standard station network or for special studies. Table 1 lists the stations, locations and operators in alphabetic order by station code (see also Figure 1).

An older regional station consists of a short-period vertical seismograph using a Willmore MK II seismometer

with a nominal one-second period. A Geotech preamplifier is used with a Geotech Helicorder to produce a visual record. Accurate timing is provided by a Sprengnether TS-100 chronometer rated against the national time service CHU or WWV. The newer stations have a Regional Modular Seismograph. This seismograph uses a Geotech S-13 seismometer, a Geological Survey of Canada preamplifier and a Geotech Helicorder. Timing is provided by a Geological Survey of Canada digital chronometer.

At Whitehorse, short-period north-south and east-west records are also produced. At Resolute both short and long-period vertical seismographs are operated; the long-period seismometer is a Geotech SL-210 with nominal 15-second period. Several regional stations have a radio telemetry link (GOB, HYT, LMQ, MNB, SIC, WGB, WKB) or telephone link (DLB, KBT, SPY) from the seismometer site to the recorder site.

Regional station calibration curves and any instrumental changes made during the year are included in Section 4 in alphabetic order by station code. Six new regional stations were added to the CSN (BBB, FST, HUO, KBB, LXQ, SXT).

2.4 Eastern Canada Telemetered Network (ECTN)

The Eastern Canada Telemetered Network (ECTN) commenced operation in 1974 with four short-period vertical outstations transmitting data to a central processing site in Ottawa via leased telephone lines. Since then the system has been expanded and, at the end of 1986 there were 21 stations transmitting data by UHF radio and/or telecommunication lines. Data concentration schemes are used for some of the more distant stations in order to reduce telephone line costs. Figures 2, 3 and 4 show the locations of seismograph stations and concentration points for the radio telemetry and telecommunications subnetworks. Table 2 lists each station with its geographical coordinates and operating dates. Stations are listed in order of their entry into the ECTN.

Table 1. Standard and Regional Seismograph Stations and Operators — 1986
(see also Tables 2 and 4)

Station Code	Station	Latitude and Longitude (degrees)	Elevation (metres)
ALE	Alert, N.W.T.	82.503 N 62.350 W	65
	Owned and operated by the Geological Survey of Canada. Station seismologist in 1986 was P. Hendry, succeeded by P. Rushforth on June 10.		
BBB*	Bella Bella, British Columbia	52.1847 N 128.1133 W	14
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by L. Bergen. The station commenced operation on December 5.		
BLC*	Baker Lake, N.W.T.	64.32 N 96.02 W	16
	Owned by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by the Radiosonde Division, Atmospheric Environment Service, Environment Canada.		
BMS*	Big Muddy Lake, Saskatchewan	49.212 N 104.793 W	419
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by S. Nyhus, Minton, Saskatchewan.		
BNB*	Barry Inlet, British Columbia	52.5758 N 131.7522 W	765
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by B. Chandra.		
CWB*	Cumshewa, British Columbia	53.1581 N 131.9967 W	620
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by B. Chandra.		
DLB*	Dease Lake, British Columbia	58.427 N 130.060 W	1210
	Owned and operated by B.C. Hydro and Power Authority. Ownership was transferred to the Geological Survey of Canada on April 1 and was subsequently operated under contract for the Geological Survey of Canada by B. Chandra.		
DWY*	Dawson City, Yukon	64.053 N 139.432 W	346
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by Mr. and Mrs. O. Blattler.		
EDM	Edmonton, Alberta	53.222 N 113.350 W	730
	Instrumented by the Geological Survey of Canada. Owned and operated by the Department of Physics, University of Alberta, with contract support from the Geological Survey of Canada.		
EFO*	Effingham, Ontario	43.092 N 79.312 W	168
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by M. Bering.		
FCC*	Fort Churchill, Manitoba	58.762 N 94.087 W	39
	Owned by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by W. Ayotte.		
FFC	Flin Flon, Manitoba	54.725 N 101.978 W	338
	Owned and operated by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by W. Kemp.		
FRB	Frobisher, N.W.T.	63.747 N 68.547 W	18
	Owned by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by the Radiosonde Division, Atmospheric Environment Service, Environment Canada.		
FSB*	Fort St. James, British Columbia	54.477 N 124.328 W	747
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by D. Hoy.		
FST*	Fort Simpson, N.W.T.	61.840 N 121.275 W	175
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by D. Balderson. The station commenced operation on January 9.		
GBN*	Guysborough, Nova Scotia	45.407 N 61.513 W	38
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by F. Lombardo.		
GDR*	Gold River, British Columbia	49.778 N 126.047 W	100
	Instrumented by the Geological Survey of Canada. Operated under contract for the Geological Survey of Canada by H.M. de Waal.

2.4.1 The outstations

The Mark I seismograph outstations consist of a Geotech S-13 seismometer with a period of 1 second, driving a signal amplifier and low-pass filter with a corner frequency of 20 Hz. The amplifier output is digitized by a 9-bit A/D converter sampling at 60 times per second. An eight-step binary gain-ranging scheme is used to extend the dynamic range while maintaining reasonable resolution. When the A/D converter senses an input signal greater than its full-scale value, the gain is reduced by a factor of two, or to a minimum gain if no intermediate gain values exist. Conversely, for an input signal less than half the full-scale value, the gain is increased by a factor of two or to maximum gain if no intermediate gain values exist. The minimum ground velocity that can be detected is 10 nanometres per second, while the maximum ground velocity is about ± 320 microns per second, giving a dynamic range of 96 decibels.

Most locations now employ the more advanced Mark II outstation package. Either a Geotech S-13 seismometer or a Willmore MK II is used. The preamplifier incorporates a switch-selectable filter usually set to pass frequencies between 1 Hz and 16 Hz. A 12-bit A/D converter is used to digitize the seismic signal 60 times per second. The gain-ranging scheme involves four selectable gains: X1, X4, X16, and X64. A microcomputer selects the highest value

of gain that can be used without overloading the A/D converter. The minimum detectable ground velocity is again 10 nanometres per second, but the largest signal that can be accommodated increases to about ±1309 microns per second, giving a dynamic range of 108 decibels.

Once each 24 hours a calibration pulse is input by applying a 1 milliampere direct current to the seismometer calibration coil for 4 seconds. Also once each 24 hours, one sample of seismic data is replaced by a special code-word that identifies the station.

2.4.2 Digital telemetry

Most outstations transmit data over dedicated, unconditioned (voice-grade) telephone lines at 1200 baud using frequency-shift-key (FSK) modulation. For remote sites where telecommunications were not feasible, UHF radio telemetry links were established for all or part of the transmission path. The carrier at radio sites is frequency modulated directly by the serialized digital signal. Figure 3 shows the current radio telemetry subnetwork.

As the network expanded the ongoing costs of telecommunications became significant. Special software and hardware were developed which could combine up to four seismic channels on a single line. A second level of signal concentration over telephone lines has been inaugurated for the eastern stations. At a concentrator site, a Gandalf SM9600 supermodem combines two 4800 bit per second streams into one 9600 bit per second stream and, using a proprietary modulation scheme, transmits data at a rate of only 40 baud. Thus, signals from up to eight seismic stations may be sent over a single, unconditioned telephone line. The current telecommunications subnetwork is presented in Figure 4.

Time delays and uncertainties are introduced by digitization, concentration and telephone line transmission of data from an outstation to the recording laboratory in Ottawa. Table 3 presents measured or theoretical values for the time delay plus uncertainty for all ECTN stations, including delays in the outstation amplifiers.

2.4.3 Central processing site

In December 1980 the ECTN Mark III system went into production in the Ottawa Datalab. A front-end LSI-11/23 microcomputer receives the incoming data stream and produces a formatted one-second data buffer. A PDP-11/34 host processor receives these data blocks and stores 5 minutes of data temporarily on disk in a ringbuffer file. A separate trigger program on the host computer continuously monitors incoming data and, when the trigger conditions are satisfied, creates an event file on disk of unfiltered digital data.

The event-detection algorithm decimates the data by a factor of two and pre-filters it with a passband of 2 to 5 Hz. The absolute value is then integrated to form a short-term average with a 4.3-second time constant and a long-term average with a 4.3-minute time constant. A trigger is declared when the short-term average exceeds a threshold, defined as a constant (typically 2 to 4) times the long-term average. Digital data from all channels are saved in the event file whenever a trigger occurs on any channel. The filter characteristics, time constants and trigger threshold may each be changed to provide different trigger conditions on a per channel basis.

Selected digital event data files are transferred to a separate VAX750 data management processor through a shared disk for subsequent off-line analysis. Hardcopy plots, reformatting, and archiving into a permanent 9-track magnetic tape library are performed on the VAX750.

The LSI-11/23 produces up to four channels of visual Helicorder records. Monitor channels and sensitivities are operator-selectable. An independent bank of dedicated microprocessors produces analogue records for up to five additional channels, with manual button selection of signal attenuation.

A parallel backup system is provided by a second LSI front end connected to the PDP-11/40. In addition, each LSI system contains a copy of its program and network configuration in ROM, allowing it to run independently of the PDP-11 and to continue to produce monitor records.

Table 3. Theoretical transmission delays for ECTN station data

Communication Link	ECTN Station	Typical Delay (Fixed & Uncertainty) (ms)
Direct radio or telephone link to Ottawa	CKO, EEO, GAC, GNT, JAQ, JBQ, MNT, OTT, SBQ, VDQ, WBO, WEO	47 — 82
One level of data concentration, no supermodem	TRQ, GRQ MNQ, HTQ	70 — 104 61 — 109
One level of data concentration using supermodems	LPQ, GSQ, EBN	198 — 233
Two levels of data concentration using supermodems	GGN, LMN, KLN	277 — 311

On June 11, 1986 the fourth-generation Canadian Digital Telemetered Seismic Network computer system was installed. This system, called ECTN Mark IV, features a single PDP-11/73 processor which replaces the LSI-11/23 front-end microcomputer and the PDP-11/34 host processor. The ring buffer has been changed to reside in memory. A direct connection to the seismic data analysis and management computer allows automatic transfer of event files as they occur. A second identical PDP-11/73 system provides a parallel backup system.

Each PDP-11/73 system produces up to twelve channels of visual Helicorder records with operator-selectable monitor channels and sensitivities. The independent bank of dedicated microprocessors has been eliminated.

Additional information on the ECTN development can be found in the annual reports by Wetmiller et al. (1986) and Hayman et al. (1985), as well as internal reports by Lyons (1980) and Lyons and Vesa (1981). Calibration curves for the monitor records and response curves for the digital data are included in Section 4 below.

2.4.4 GAC SRO-type borehole seismometer

At Glen Almond, Québec (GAC), a Geotech model 36000 triaxial seismometer is installed at a 100-metre depth in a cased borehole. The digital short-period and long-period signals are incorporated into the ECTN data acquisition system. At the outstation the three short-period signals are each digitized at 30 samples per second and the three long-period signals at one sample per second. The respective passbands are shown on the GAC calibration curves. The data are transmitted to Ottawa by radio telemetry at a rate of 1800 baud.

The ECTN trigger algorithm monitors only the short-period vertical component, but all three short-period components are saved during an event. Continuous three-component long-period data are saved separately and permanently on magnetic tape. Copies of these tapes are sent to the Albuquerque Seismological Laboratory in Albuquerque, New Mexico, where they are merged with data from other seismic research observatories (SRO).

2.4.5 Sudbury Local Telemetered Network (SLTN)

In 1984, an autonomous local event processor was installed at the Science North museum in Sudbury, Ontario, for public display. Modelled on the ECTN, the SLTN system processes the data telemetered from a Mark II ECTN outstation, SUO, deployed in the rural area south of the city. Detected events, stored on a local disk, are transferred to Ottawa daily over a dial-up 9600-baud telephone link for editing and merging with the ECTN data set. A custom version of the ECTN Seismic Analysis Monitor software (SAM) provides automatic graphics display of the last triggered event and limited on-site event analysis.

Table 4. Western Canada Telemetered Network Stations — 1986

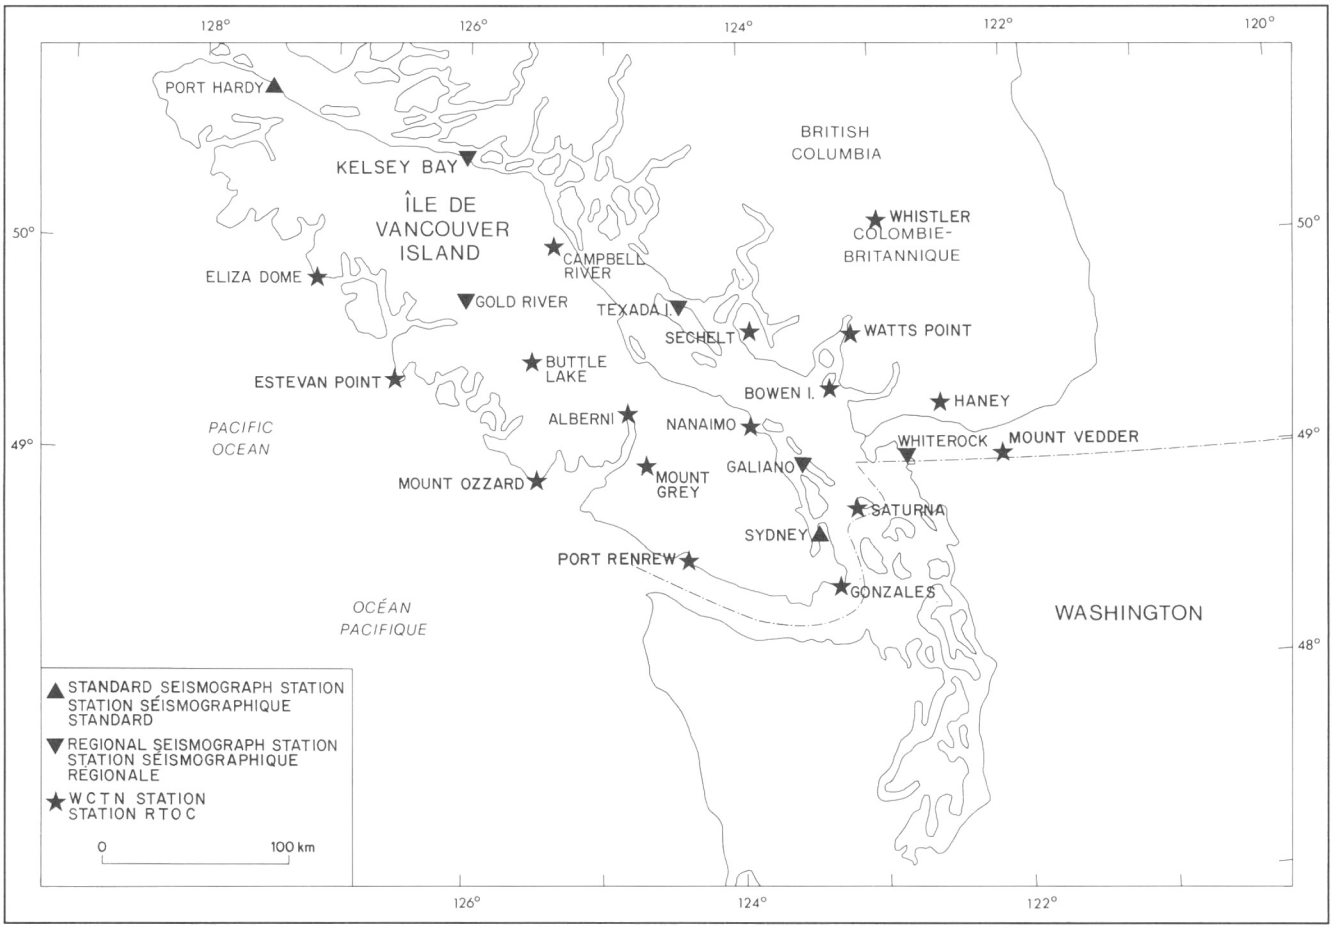

Figure 5. Western Canada Telemetered Network and Other Stations - 1986.

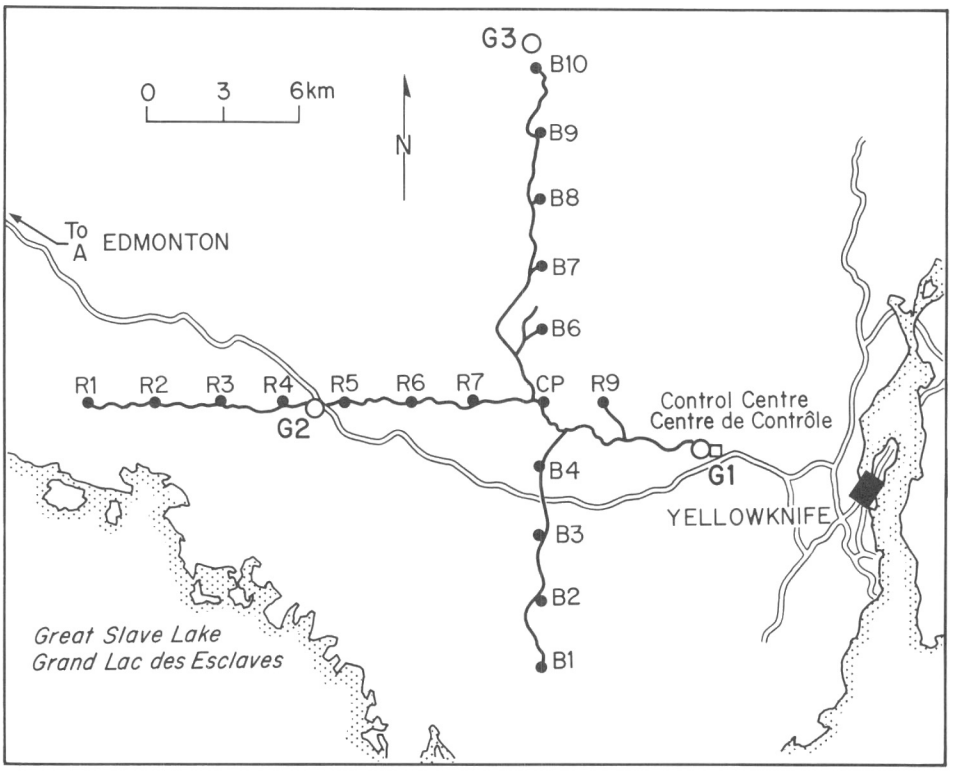

Figure 6. Yellowknife Seismograph Array - 1986

2.5 *Western Canada Telemetered Network (WCTN)*

The Western Canada Telemetered Network, which commenced operation in 1975, consisted of four short-period vertical outstations connected to Victoria by telephone lines. Sidney replaced Victoria in mid-March 1978. At the end of 1986 the network consisted of 18 stations transmitting data by UHF radio and/or telecommunication lines. Table 4 gives a list of the stations with their coordinates and operating dates and Figure 5 shows their locations.

In October, 1986, the WCTN central site hardware and software were upgraded to the Mark IV level currently used in the ECTN.

The outstations, computer system, data recording and storage are similar to those of the ECTN.

Calibration curves for the monitor stations and digital data response curves are included in Section 4.

2.6 *Yellowknife Array*

The medium-aperture, short-period vertical array at Yellowknife, N.W.T., has operated since 1962. The array configuration is shown in Figure 6. The eighteen Willmore Mark II vertical seismometers with a nominal one-second period have a 2.5 km spacing. A nineteenth short-period vertical seismometer and two short-period horizontal seismometers are located in the Yellowknife standard station vault (YKC), which is indicated on Figure 6 as site G1.

In addition to the short-period array, a long-period tripartite array consisting of Geotech SL210 long-period vertical seismometers is located at sites G1, G2 and G3. Site G1 also contains two Geotech SL220 long-period horizontal seismometers and a single-component vertical broadband seismometer. These seismometer signals are recorded on FM tape only.

The outstation electronics package includes a VHF transmitter, receiver, diplexer, amplifier, calibrator and power inverter housed in a case insulated with 15 cm of polystyrene to reduce the effect of environmental extremes. Data are transmitted to the Control Centre by a frequency-modulated audio subcarrier. Power is obtained from a thermoelectric generator which burns propane from a 1000-litre tank which is refuelled annually. Because of the extremely low temperatures in winter (-40°C) a nitrogen tank is required to pressurize the propane tank.

At the Control Centre, the on-line digital processing system, called the Canadian Seismic Array Monitor (CANSAM) is built around a PDP-11 minicomputer. The system remotely monitors and calibrates the various seismic sensors, digitizes the short-period signals at 20 samples per second, forms 121 beams in real time and processes the data with a detection algorithm. Detected events are saved on 9-track digital tape. A detection log is saved on disk with a hard copy log printed on a teletypewriter and punched in parallel on paper tape. The detection log is regularly transferred to Ottawa by a dial-up data link. Analogue FM tape is used to provide a continuous backup to the digital system and for additional data processing off-line in Ottawa. Helicorders are used to monitor one short-period channel, one long-period channel, a fifteen-minute sequential sample of all channels and the last beam to trigger.

Additional information on the Yellowknife array history, developments and current configuration can be found in reports by Manchee and Somers (1966), Manchee

Table 5. Special or temporary stations — 1986

Station Location	Coord. (degrees)	Operating Dates	Description
Charlevoix Array La Pocatière, Qué.	47.5 N 70.0 W	Aug. 30/77 to date	6-element (3 on north shore, 3 on south) telemetered array recording on analogue tape
Nahanni, N.W.T.	62.2 N 124.2 W	January 2/86 to January 8/86	6 short-period vertical sprengnether MEQ-800 seismographs and 3 GSC digital seismographs for an aftershock survey
Nahanni, N.W.T.	62.2 N 124.2 W	September 12/86 to September 21/86	8 short-period vertical Sprengnether MEQ-800 seismographs and 5 GSC digital seismographs for an aftershock survey
Nahanni, N.W.T.	62.2 N 124.2 W	October 13/85 to date	3 Kinemetrics SMA-1 accelerographs at various locations

and Hayman (1972) and Weichert and Henger (1976). Response curves for the shortand long-period array and the broadband seismometer are included in Section 4.

2.7 Special or Temporary Stations

To supplement the existing permanent seismograph networks of the Geological Survey of Canada, special or temporary installations are commissioned at different sites for varying lengths of time. Table 5 gives the locations and operating dates for these stations plus a brief description of the type of installation.

2.8 Strong-Motion Seismograph Networks

Strong-motion instruments in Canada are organized into two networks, one in eastern Canada maintained by the Geophysics Division of the Geological Survey of Canada and one in western Canada (including one station in northern Canada) maintained by the Cordilleran and Pacific Geoscience Division of the Geological Survey of Canada. At the end of 1985 there were 76 accelerographs deployed in the two networks. The 58 accelerograph sites described in the accompanying Table 6 are listed in chronological order of initial installation. (Some sites have been closed and subsequently reopened.)

For a description of the strong-motion program see Weichert and Munro (1987). For a report on all Canadian strong-motion records to 1979, see Weichert and Milne (1980). For a report on the analysis of the Miramichi accelerograms, see Weichert et al. (1982). For reports on the analysis and discussion of the Nahanni accelerograms see Weichert et al. (1986) and Wetmiller et al. (1987).

TABLE EXPLANATION

LOCATION
Closest community followed by site name.

DATE
Installation date of first instrument at site.

COORDINATES (COORD)
Latitude (N) and longitude (W) are listed to the nearest 0.01 degree. Where they are not known that accurately they are listed to the nearest 0.1 degree. For eastern Canada, coordinates supplied in degrees and minutes have been converted to the nearest 0.01 degree.

INSTRUMENT (INSTR)
United Electro Dynamics AR-240, Teledyne-Geotech RFT-250, Kinemetrics SMA-1.

SENSITIVITY (SENS)
Full-scale sensitivity of the instrument expressed as multiplier of the acceleration of gravity (g).

TRIGGER
Triggering level. The AR-240 and RFT-250 have horizontal displacement triggers. The SMA-1 has a vertical trigger sensitive to acceleration in the 1 to 10 Hz bandwidth. Where the acceleration level is listed as 0.01 g, the instrument has not been field calibrated and is assumed to be at the factory-set level.

OWNER

EMR	Energy, Mines and Resources Canada
NRC	National Research Council of Canada
HQ	Hydro-Québec
BCHPA	British Columbia Hydro and Power Authority
AECL	Atomic Energy of Canada Limited

3. CANADIAN SEISMOLOGICAL DATA

3.1 Standard and Regional Station Procedures

Seismograms from all stations are mailed weekly to Ottawa or the Pacific Geoscience Centre (PGC). On a weekly basis standard stations submit phase report sheets listing the arrival times of all P phases of teleseisms and also local earthquakes equal or greater than magnitude three. Local earthquake monthly summary sheets, seismogram log sheets and instrument and equipment log sheets are submitted from standard stations monthly. Regional stations submit only monthly seismogram log sheets, instrument and equipment log sheets. Quality control on station seismograms, data and log sheets is performed by Network staff in Ottawa or PGC prior to having the seismograms microfilmed.

3.2 Rapid Telex Data

All Canadian standard seismograph stations forward readings to Ottawa five days a week via telegraph, telecopier or intercomputer communications. These readings include P-wave onset times from most teleseisms and from local earthquakes of magnitude three or greater. If the peak-to-peak trace amplitude of a teleseismic P-wave exceeds four millimeters during the first minute, then the period and the maximum zero-to-peak ground amplitude are both reported. Selected high-gain stations telegraph periods (in seconds) and ground amplitudes (in millimicrons) for all teleseisms. This procedure was adopted to improve the determination of m_b for smaller events. Additional information, such as pP phase arrival times and P-wave first motions of teleseisms, are telegraphed when they are clearly recorded. For local earthquakes of magnitude three or greater, the maximum trace amplitude of the S or Lg phase, and the corresponding period, are included with the P-wave arrival time in the telegraphed message. Only the P-wave arrival times from these messages are relayed to other seismological institutions.

The U.S. Geological Survey, National Earthquake Information Service (NEIS), continues to make immediate use of the Canadian P-phase data in their fast epicentre determinations. The telegraphed data from Canadian standard stations are made available with limited checking to NEIS, within 48 hours of their arrival in Ottawa. The P-wave data are stored temporarily in the departmental computer in Ottawa. These data are then accessed by NEIS using a teletype terminal and telephone lines. Copies of the telegraphed P-wave arrival data are airmailed to Britain, Sweden and the U.S.S.R. for use of seismological institutions in those countries. NEIS relays Canadian data to the International Seismological Centre for inclusion in the ISC definitive calculations.

3.3 Microfilm

Thirty-five millimetre negative microfilm rolls of Canadian seismograms from standard and some selected regional stations (WHC, BLC, SKB and LMQ) are stored in Ottawa and PGC. In addition the records from all the stations (regional and standard) are microfilmed together on a single roll for significant local events (magnitude at least 4). Copies of Canadian seismogram microfilm from January 1, 1962, to the present have been deposited with the World Data Center A for Seismology, Environmental Data Service, NOAA, Boulder, Colorado, 80302, U.S.A. Present scheduling permits film to be in the World Data Center A within four months of the current date. Microfilm of records prior to 1962 is available to cooperating institutions on request to the Head, Canadian Seismograph Network, Geophysics Division, Geological Survey of Canada, Energy, Mines and Resources Canada, Ottawa, Canada, K1A 0Y3.

3.4 Original Seismograms

Original seismograms are normaliy available only to qualified Canadian research scientists, since microfilm is available at Boulder, Colorado, to all others. On special request to the Director, Geophysics Division, Geological Survey of Canada, Energy, Mines and Resources Canada, Ottawa, Canada, K1A 0Y3, original Canadian seismograms may be loaned to qualified foreign requesters. This loan, in general, can be made only after the seismograms have been photographed; this avoids undue delay in depositing complete microfilm from the Canadian Seismograph Network in the World Data Center for use of all scientists.

Original Canadian seismograms dating back to and including 1899 are stored in Ottawa.

3.5 Data Management

The Seismological Data Laboratory at Ottawa maintains analogue and digital tape libraries. Analogue FM field tapes are normally recycled within a year. Long-term storage is usually in the form of edited digital event files. These libraries include event files from the Eastern and Western Canada Telemetered Networks and from the short-period Yellowknife Array CANSAM processor, events recorded on the long-period digital tape system in British Columbia from August 3, 1972 until October 28, 1975, digitized and processed accelerograms from the New Brunswick and Nahanni strong-motion arrays (Weichert et al., 1982 and Weichert et al., 1986), and specialized data from limited duration field surveys or special seismograph installations. The format of these digital event files varies depending on the data, the recording method and the computer operating system, but in all cases the data can be reformatted on special request.

3.6 Special and Digital Data

Data and records from seismograph installations other than the standard and regional networks are available on special request to the Head, Canadian Seismograph Network, Geophysics Division, Geological Survey of Canada, Energy, Mines and Resources Canada, 1 Observatory Crescent, Ottawa, Ontario K1A 0Y3. These records and data include those produced from special or temporary seismograph installations and all data processed in the Data Laboratory. A charge is made for accessing and copying digital data.

3.7 Canadian Earthquakes

All significant earthquakes occurring in or near Canada are located by the Geological Survey of Canada in Ottawa or Sidney. A quarterly bulletin of Canadian earthquakes is produced approximately six months in arrears and distributed to cooperating institutions. An annual catalogue of Canadian earthquakes is produced for each calendar year. A composite digital tape file, the Canadian Earthquake Epicentre File, is also maintained and updated each year. All Canadian earthquake determinations with magnitude greater than three, with their associated data, are submitted to the ISC for inclusion in its bulletin.

4. SEISMOGRAPH STATION INSTRUMENTATION

4.1 Instrument Changes During 1986

Instrument changes or calibrations were performed during 1986 at the following stations, listed in alphabetic order by their code. For any changes that resulted in more than one calibration curve being applicable during the year, the appropriate additional curves are included here. New stations are calibrated on the day of installation, unless otherwise indicated.

Alert (ALE). From November 20 to 26 the standard station was closed for calibration and maintenance. The "As Found" calibrations were very similar to the previous 1982 calibrations and all the seismographs were left as found.

Bella Bella (BBB). On December 5 a short-period vertical Regional Modular Seismograph commenced continuous operation at Bella Bella, British Columbia. The station was installed to improve the monitoring of seismicity in the Hecate Strait-Queen Charlotte Sound vicinity.

Churchill (FCC). From June 9, 1984, to June 18, 1986, the station had reversed polarity.

Flin Flon (FFC). From January 4 to December 10 the calibration pulses of both of the long-period horizontal seismographs were reduced in amplitude by half due to wiring difficulties. On November 27, the long-period north-south galvanometer was replaced.

Fort St. James (FSB). The regional station was closed for the day on September 21 for calibration and maintenance.

Fort Simpson (FST). On January 9 a short-period vertical Regional Modular Seismograph commenced continuous operation at Fort Simpson, Yukon Territory. The station was installed to improve the monitoring of the Nahanni earthquake sequence.

Saint George (GGN). A new seismometer with reversed polarity was installed on February 7, 1984. The polarity was reversed until June 18, 1986.

Grand-Remous (GRQ). On October 23 the ECTN station was calibrated "As Found", a new seismometer was installed and a "Final" calibration was done.

Halifax (HAL). From April 16 to May 5 the seismograph response was 38 % lower than the calibrated level due to a loss of sensitivity in the galvanometer. The station was closed from May 5 to 6 when a new Regional Modular Seismograph was installed.

Hauterive (HTQ). The ECTN station was inoperative from December 6, 1985 to January 29, 1986, and again from February 15 to 20 due to failures of the telemetry system. From June 19 to July 8 the station was inoperative due to a telecommunications concentrator failure.

Hudson (HUO). On October 2 a short-period vertical Regional Modular Seismograph commenced continuous operation at Hudson, Ontario. The station replaces the closed Sioux Lookout Station.

Inuvik (INK). From August 12 to 16 the standard station was closed for calibration and maintenance. The "As Found" calibrations were very similar to the previous 1981 and 1982 ones and all the seismographs were left as found.

La Grande-3 (JAQ). From November 15 to 16 the ECTN station was closed for maintenance.

Kelsey Bay (KBB). On August 23 a Geotech short-period vertical analogue regional type seismograph recording on a Helicorder commenced continuous operation at Kelsey Bay, British Columbia. The station was installed to improve the monitoring of seismicity on Vancouver Island.

Komakuk Beach (KBT). The regional station was calibrated on August 16.

McKendrick Lake (KLN). On November 18 the ECTN station was calibrated.

Thunder Bay (LHC). The standard station was permanently closed on September 24. The "As Found" calibrations were very similar to the previous 1983 ones.

Caledonia Mtn. (LMN). On November 20 the ECTN station was calibrated.

La Grande-3 (LRQ, LXQ). On October 16 the regional station, LRQ, at La-Grande-3 was closed. The equipment was installed in the vicinity at a new site, LXQ, and commenced continuous operation on December 15.

Mould Bay (MBC). From August 13 to 18 the standard station was closed for calibration and maintenance. The "As Found" calibrations were very similar to the previous 1982 ones. The short-period seismographs were left as found while the long-period vertical seismograph was raised slightly to more closely match the response of the other long-period components.

Manicouagan (MNQ). The ECTN station was inoperative from December 6, 1985 to January 29, 1986, and again from February 15 to 20 due to failures of the telemetry system. The Mark I outstation was replaced by a Mark II outstation on March 4. From March 14 to April 1 the station was inoperative due to a power supply failure. From June 19 to July 8, the station was inoperative due to a telecommunications concentrator failure.

Penticton (PNT). From August 22 to 26 the standard station was closed for calibration and maintenance. The "As Found" calibrations were very similar to the previous 1982 ones and all the seismographs were left as found.

Resolute (RES). The regional station was closed for calibration and maintenance from September 19 to 20.

Suffield (SES). On November 21 the long-period north-south galvanometer was replaced. From November 21 to 24 this component had reversed polarity.

Shingle Point (SPY). The regional station was calibrated on 16 August.

Sudbury (SUD). The regional station was closed on July 3.

Sachs Harbour (SWT, SXT). On August 11 the regional station, SWT, at Sachs Harbour, Northwest Territories was closed. The station had been inoperative since June 30. The equipment was installed in the vicinity at a new site, SXT, and commenced continuous operation on August 13.

Sioux Lookout (SXO). The station was closed from the beginning of the year to March 5 due to persistent instrumentation problems, and, finally, it had to be completely reinstrumented. The regional station was closed on September 24. The equipment was installed at Hudson, Ontario, on October 2.

Mont-Tremblant (TRQ). On October 22 the ECTN station was calibrated.

Val-d'Or (VDQ). The ECTN station was closed on April 18.

Whitehorse (WHC). From August 18 to 19 the regional station was closed for calibration and maintenance. The three older regional seismographs were calibrated and decommissioned and were replaced by Regional Modular Seismographs. The new units were calibrated on August 20. There was a fault in the suspension of the east-west seismometer and the calibration is unreliable until the installation of a new one on September 15 at 2315 (U.T.). The north-south seismograph was inoperative from December 2 to 29 due to a Helicorder failure. The unit was returned to Ottawa for repair and calibration.

Blue River (WGB). The regional station was closed on July 31.

Yellowknife (YKC). From September 21 to 22 the standard station was closed for calibration. The "As Found" calibrations were very similar to the previous 1981 ones and all the seismographs were left as found.

4.2 Calibration Curves

Calibration curves for all permanent seismograph stations, listed alphabetically by station code, are given on the following pages. The curves for the photographic seismographs were obtained by application of the Willmore bridge method on site (Willmore, 1959). Telemetered and regional station calibration curves are usually computed in Ottawa from the measured seismograph system parameters. Theoretical or calculated response curves are shown by dashed lines while dots represent values measured in situ. Magnification and acceleration sensitivity of any seismograph are determined from the curves by multiplying the velocity sensitivity by $2\pi/T$ and $T/2\pi$, respectively.

The calibration sheets give the periods of the seismometers and galvanometers, the filter frequencies, and other information such as the station coordinates, altitude, geological formation and date of calibration. Where the seismograph uses electronic amplification, the calibration curves indicate the preamplifier and amplifier settings and also, where applicable, the preamplifier mode of operation-either constant magnification (MAG) or constant velocity sensitivity (VEL). Response curves for computer-produced

monitor records give a computer (Monitor) gain factor. Those for microprocessor-produced records show the key-pad button (BUT) selection of signal attenuation plus amplifier setting.

5. PERSONNEL

During 1986, Mr. R.J. Halliday was in charge of the operation of the Canadian Seismograph Network and was assisted in quality control and in network and data management by Mr. W.E. Shannon and Mr. D.J. Schieman in Ottawa and by Dr. D.H. Weichert, Mr. R.B. Horner and Dr. G.C. Rogers at the Pacific Geoscience Centre. Mr. P.S. Munro was responsible for station maintenance and calibration of CSN stations and also of the eastern strong-motion network.

Research and development of ECTN, WCTN and other instrument systems is done in the Ottawa Seismological Instrumentation Laboratory under the direction of Mr. D. Trigg. In particular, Mr. F. Andersen has been responsible for the design of ECTN/WCTN outstation hardware and software. Mr. J. Thomas has been responsible for the construction, deployment, overhaul and repair of all instrumentation systems.

In the Ottawa Datalab Mr. J.A. Lyons has been responsible for ECTN/WCTN software development. Mr. W.E. Shannon and Ms. D. Higgs have been responsible for the daily ECTN operation. Mr. A. Vesa has looked after hardware maintenance of the datalab equipment since the inception of ECTN.

At the Pacific Geoscience Centre Mr. M. Bone has overall responsibility for instrumentation; he was assisted by Mr. A. Whitford. Mr. R. Baldwin, Mr. M. Wilde and Mr. M. Gregory have been responsible for the daily WCTN operation.
