

NOTE: This legend is common to Open File 405, 406

MIDDLE ORDOVICIAN		APHEBIAN OR HELIKIAN	
35	TRENTON GROUP: Limestone	16	16a Granodiorite
34	BLACK RIVER GROUP: Limestone	16	16b Granite
33	ROCKLIFE: sandstone, shale, limestone	15	15a Migmatite
LOWER ORDOVICIAN		15	15b Biotitic migmatite
32	OXFORD: dolomite	15	15c Biotitic quartzofeldspathic gneiss
31	MARCHE: sandstone, dolomite	14	14 Quartzofeldspathic gneiss, leucogranulite
30	NEPEAN: sandstone	PROTEROZOIC	
CAMBRIAN		13	13a Biotite gneiss
29	THERESEA: sandstone, dolomite	13	13b Hornblende-biotite gneiss
HELIKIAN		12	12 Hornblende-garnet-biotite gneiss
28	28a Syenite	11	11 Silicified-garnet-biotite gneiss
28	28b Hornblende syenite	10	10 Hornblende gneiss
28	28c Nepheline syenite	9	9 Biotitic quartzofeldspathic gneiss
27	27a Granite	8	8 Biotitic migmatite
27	27b Potassic granite	7	7 Amphibole-hypersthene gneiss
27	27c Biotitic potassic granite	ARCHAIC OR PROTEROZOIC	
27	27d Hornblende potassic granite	6	6a Potassic granite
26	26a Gabbro	6	6b Biotitic potassic granite
26	26b Diorite	5	5a Gabbro
26	26c Diorite	5	5b Diorite
25	25a Amphibolite	4	4 Paragneiss
25	25b Hornblende gneiss	3	3 Hornblende gneiss
24	24a Amphibolite	2	2 Migmatite, granitic gneiss
24	24b Hornblende gneiss	1	1 Amphibole-hypersthene gneiss
23	23a Amphibolite	FAULTS	
23	23b Hornblende gneiss	Dyke

Geology derived from the map 1334-A, Rivière Gatineau at the scale of 1:1,000,000. Compiled by A.J. Bear, W.H. Poole and B.V. Sandford, 1971

Geological cartography by the Geological Survey of Canada

Base-map at the same scale published by the Mapping and Charting Establishment, M.C.E. 1958-61

Mean magnetic declination 1977, 11043.8' West decreasing 0.1' annually. Readings vary from 12933' in the S.E. corner to 10958.8' in the NW corner of the map area

Elevation in feet above mean sea-level

Geochemical Symbol and Data Presentation

The concentration of an element at a sample site is graphically represented as one of 15 symbols, if a sample was collected but there is no data available a dot is plotted. The symbols are symmetrically arranged so that they first increase in size to the eighth symbol and then increase in blackness to the fifteenth. The two small crosses at the low end of the scale are used to respectively denote concentrations below the analytical detection limit, or, in the data group containing the detection limit. The data are grouped on a semi-logarithmic scale, i.e. 1, 2, 5, 10, 20, 50, 100 etc. Five decades can be spanned and this arbitrary division has been chosen for the continuing Canada wide series of maps constituting the National Geochemical Reconnaissance. The choice of symbols and the data groups they represent for any specific element is based on the histogram and cumulative frequency plot for the total survey data from one, or more contiguous, open file sheets covered in one field season. The eighth symbol is used for the model group as defined by the histogram, this group usually includes the median of the data as defined by the 0.5 (50%) point on the cumulative frequency plot. Some, or all, of the remaining 14 symbols are chosen so as to achieve an appropriate graphical impact. An example of all 15 symbols is given below.

The symbol maps, being based on the total survey data distributions, are unaffected by the availability of ever increasing levels of knowledge in bedrock and surficial geology, and other environmental factors. Therefore, the raw data symbol maps are only intended to assist the rapid inspection of the data for gross regional features. To fulfil the needs of a more specific and thorough interpretation, the raw data symbol maps should be modified using the field and analytical data provided in the data listings and any other knowledge available. To assist in the appraisal and modification of the data in terms of the symbol map bedrock geology, a table of summary statistics and proposed threshold values for each mapped bedrock unit, or broad lithologic unit, again based on the total survey data, is presented below the histogram. This table can be used along, or in conjunction, with the sample location map and data listings to indicate above threshold samples where they occur on the map. In many instances, the table will also illustrate, more clearly than the map, the dependence of mean geochemical levels on bedrock type. It may often be also observed that whilst the total data appears to approximate a log-normal distribution the data for individual map or lithologic units appears to approximate a normal distribution. The proposed thresholds presented are believed to be useful in interpreting the data from a mineral exploration viewpoint. Locations of samples with concentrations in excess of the threshold for the rock unit they appear to be derived from, should be studied carefully. The above threshold concentration can be due to a wide range of geological and environmental factors, but one of these could be the presence of abnormal concentrations of the element in a form of interest to the mineral explorationist.

To comprehensively study an area, all available geological, environmental and recorded data should be utilized. The data separation by bedrock type can often be improved by constructing new data subsets and deriving local threshold levels based on the most detailed and up-to-date knowledge available.

The term reliability factor and value that appears below the table is an estimate of the reliability of the geochemical map. On the basis of duplicate sampling 5% of all lakes sampled it can be stated that there is a 95% chance that if any lake is resampled and identical methods of sample preparation and analysis are used the new value will lie between $X + RF$ and $X - RF$ where X is the original value obtained. This factor takes into account variability due to both heterogeneity of the centre-lake bottom sediments and sample preparation and analytical causes.
