LEGEND

Note: This legend is common to National Geochemical Reconnaissance Map 9-1976, Open File 413, Map10-1976, Open File 414 and Map11-1976, Open File 415

PELICAN

Pgy Gabbro, meta-gabbro and diabase dykes [DEVO]

P Diorite, quartz monzonite and granodiorite (Guthrie Lake granite) [DART] APHEBIAN

PM Granite, quartz monzonite and granodiorite [EPM]

PM Lithic greywacke to subgreywacke [EPM]

PM Conglomerate [EGM]

PF Arkose to subgreywacke [EAVL]

PF Lutite, quartz lutite,dolite and tuff [ECIT]

PF Paragneiss, pyroxenite, calc-silicate bands derived from PE [EMMC]

PE Undivided PE, PD and PC [EMMC]

PD Dolomite, limestone and other argillite, phyllite [EMMC]

PD Gabbro sills [EGMC]

PC Argillite, phyllite, greywacke, some minor dolomite [EMMC]

PC Quartzite, orthoquartzite [EMQT]

PC Greywacke-conglomerate, greywacke, protoquartzite [LIAK]

ARCHEAN

Ag Meta-gabbro dykes [MGAB]

Z Quartz monzonite, granodiorite and granite, massive to foliated [GLMC]

A Diorite and gabbro [GDRT]

Z Grey biotite granodiorite gneiss [GBNG]

A Paragneiss, minor paraschist [PRGS]

A Amphibolite, amphibolite gneiss [AMPG]

A Greywacke, greywacke-conglomerate, argillite, phyllite, minor tuff [GRCK]

A Meta-volcanic rocks [MVCC]

Drift-covered area.....
Geological contact.....
Fault.....
Limit of geological mapping.....
Esker; (direction of flow known).....
Mineral occurrence.....dx

Legend modified and geology derived for the geochemical map by R.G. Garrett from maps 26-1970, 3-1972 and 4-1972 and B.D.C. Paper 74-54 Dr. E.I. Eade

Geological cartography by the Geological Survey of Canada

Base-map at the same scale published by the Mapping and Charting Establishment, M.C.E., 1966

Mean magnetic declination 1977, 0°58'E decreasing 2.4' annually. Readings vary from 1°22.8' in the SE corner to 1°03.4' in the NW corner of the map area

Elevation in feet above mean sea-level

Geochemical Symbol and Data Presentation

The concentration of an element at a sample site is graphically represented as one of 11 symbols, if a sample was collected but there is no data available a dot is plotted. The symbols are symmetrically arranged so that the area occupied increase in size by the eighth symbol and then increase in blackness to the fifteenth. The two small crosses at the low end of the scale are used to respectively denote the presence of Mo and Ag. The class limits are not linear, i.e. in the data presentation tabulating the particles finer. The class limits are grouped on a semi-logarithmic scale, i.e. 1,2,5,10,20,50,100 etc. Five decades are represented on the legend and calculation has been chosen for the continuing Canada wide series of maps constructing the National Geochemical Reconnaissance.

The choice of class limits and the data groups they represent for any specific elements is based on the histogram and cumulative frequency plot for the total survey data from one, or more, provinces. Sometimes a single survey may not provide a good basis. The eighth symbol is used for the median group as defined by the histogram, this group usually includes the median of the data as defined by the 0.5 (50%) point on the cumulative frequency plot. Some, or all, of the remaining 14 symbols are chosen so as to achieve an appropriate graphical impact. An example of all 15 symbols is given below.

The symbol maps, being based on the total survey data distributions, are unaffected by the availability of ever increasing levels of knowledge in bedrock mapping and the influence of many environmental factors. Therefore, the raw data symbol maps are only intended to assist the rapid inspection of the data for gross regional features. To fulfil the objectives of the map series, the following publications, the raw symbol maps should be modified using the field and analytical data provided in the data listings and any other knowledge available. To assist in the modification of the symbol maps, data in terms of the symbol map density groups, a table of summary statistics and proposed threshold values for drainage samples, dominantly derived from each mapped bedrock unit, is presented below. Background data on the total survey data, is presented below the histogram. This table can be used along, or in conjunction, with the sample location map and data listings to produce modified symbol maps. Comments, if any, occur on the map. In many statistics, the table will also indicate clearly that the map, the dependence of mean geochemical levels as bedrock type changes, is not a valid concept. That within the total data appears to approximate a log-normal distribution the data for individual map or lithologic units appears to approximate a normal distribution. The histogram and cumulative frequency presentation are believed to be useful in interpreting the data from a mineral exploration viewpoint. Locations of samples with concentrations in excess of the threshold values may be of particular interest to be derived from, should be outlined. The data separation by bedrock type can often be improved by constructing new data subsets and deriving local threshold values in terms of the additional knowledge available.

The term reliability factor and value cited in the table below the table is an estimate of the reliability of the geochemical maps. It is the probability that the sampling to of all lakes sampled it can be stated that there is a 95% chance that if any lake is resampled and identical methods of sample preparation and analysis are employed, the result will be between 1 / RF and 1 x RF where X is the original value obtained. This factor takes into account variability due to both heterogeneity of the centre-lake bottom sediments and sample preparation and analytical causes.
