LEGEND

Note: This legend is common to National Geochemical Reconnaissance Map 5-1976, Open File 415; Map10-1976, Open File 434 and Map15-1976, Open File 435

KILLISNOO
19 Gabbro, meta-gabbro and diabase dykes [DEVO]
18 Granite, quartz monzonite and granodiorite (Sealtish Lake granite) [DEVT]
ANVILIAN
20 Granite, quartz monzonite and granodiorite [ELMO]
19 Lithic greywacke to subgreywacke [DEVO]
16 Conglomerate [SILM]
17 Diorite to subgreywacke [ANVI]
16 Lavite, quartz latite, dacite and tuff [DEVT]
15 Pyroxenites, amphibolites, meta-ultrafute bands derived from 14 [UMBA]
14 Undivided 11, 12 and 13 [UMBA]
13 Dolomite, limestone and minor argillites, phyllites [UMBA]
12 Gabbro sills [DIKE]
11 Argillites, phyllites, greywacke, some minor dolomite [UMBA]
10 Quartzites, orthoquartzite [UNDI]
9 Greywacke-conglomerate, pyroxenite, ultramafic [ILIAC]
ARCHEAN
8 Meta-gabbro dykes [MAFI]
7 Quartz monzonite, granodiorite and granite, massive to foliated [ELMO]
6 Diorite and gabbro [DIOR]
5 Grey biotite granodiorite gneiss [GRNS]
4 Paragneiss, minor paraschist [PRGS]
3 Hornblende, amphibolite gneiss [AMPG]
2 Greywacke, greywacke-conglomerate, argillite, phyllite, minor tuff [GRCG]
1 Meta-volcanic rocks [MVCC]

Drift-covered areas.....
Geological contact.....
Fault.....
Limit of geological mapping.....
Tokens (direction of flow known).....
Mineral occurrence.....

Legend modified and geology derived for the geochemical map by R.G. Garnett from maps 24-1970, 2-1972 and 4-1972 and G.S.C. Paper 74-58 BY. E.C. Lode

Geological cartography by the Geological Survey of Canada

Base-map at the same scale published by the Mapping and Charting Establishment, M.C.E., 1966

Mean magnetic declination 1977, 0°58'E decreasing 2.4' annually. Readings vary from 0°02.8' in the SE corner to 1°52.4' in the NW corner of the map area

Elevation in feet above mean sea-level

Geochemical Symbol and Data Presentation

The concentration of an element at a sample site is graphically represented as one of 15 symbols. If a sample was collected but there is no data available a dot is plotted. The symbols are symmetrically arranged so that they first increase in size in the eight octants and then increase in blackness in the fifteenth. The two small crosses at the low end of the scale are used to respectively denote the presence of the element in a sample but in an amount too low to measure, or falling the detection limit. The data are grouped on a semi-logarithmic scale, i.e. 1,2,5,10,20,50,100 etc. Five decades can be spanned and this arbitrary division has been chosen for the continuing Canada wide series of maps constituting the National Geochemical Reconnaissance.

The selection of the class interval groups they represent for any specific element is based on the histogram and cumulative frequency plot for the total survey data from one, or more contiguous, open file sheets covered in one field season. The eighth symbol is used for the model gross as defined by the histogram, this group usually includes the medians of the data as defined by the G.S (SOC) Paper 74-58 and Statistical Report 2. Some, or all, of the remaining 14 symbols are chosen so as to achieve an appropriate graphical impact. An example of all 15 symbols is given below.

The symbol sizes, being based on the total survey data distributions, are unaffected by the availability of ever increasing levels of knowledge in bedrock and overburden. The geochemical symbol map is designed for use on the data symbol maps are only intended to assist the rapid interpretation of data for gross regional features. To fulfil the needs of a more specific and thorough interpretation, the maps symbol maps should be modified using the field and analytical data provided in the data listings and any other knowledge available. To assist in the modification of the symbol maps, the data listings and symbol map bear geological, a table of summary statistics and proposed threshold values for drainage samples dominantly derived from each mapped bedrock unit, or subunit. The thresholds are based on the total survey data, is presented below the histogram. This table can be used along, or in conjunction, with the sample location map and data listings to locate areas of anomalous concentrations where they occur on the map. In many instances, the table will also indicate thresholds, clearly than the map, the dependence of mean geochemical levels on certain specific rock types. It is recommended that within the total data appears to approximate a log-normal distribution the data for individual map or lithologic units appears to approximate a normal distribution. The thresholds recommended are believed to be useful for interpreting the data from a mineral exploration viewpoint. Locations of samples with concentrations in excess of the threshold may be worthy of further note to be derived from, should be studied carefully. The above threshold concentration can be due to a wide range of geological and environmental factors, but one of the most likely is that anomalous concentrations are believed to be useful for interest to the mineral exploration viewpoint.

To comprehensively study an area, all available geological, environmental and recorded data should be utilized. The data separation by bedrock type can often be imposed by constructing new data subsets and deriving local threshold levels for each bedrock unit. This is a task for the user of the maps.

The form multiplicity factor and value that appears below is likely to an estimate of the reliability of the geochemical map. On the basis of duplicate sampling 95 of all holes sampled it can be stated that there is a 95% chance that if any lake is resampled and identical methods of sample preparation and analysis are employed the value will be between 1-7 DF and 1 x DF where X is the original value obtained. This factor takes into account verifiability due to both heterogeneity of the centre-lake bottom sediments and sample preparation and analytical causes.
