LEGEND

Note: This legend is common to National Geochemical Reconnaissance Map Nos. 74 Great Fish Hill, Map 75-1976, Open File 414 and Map 71-1976, Open File 415.

MESOZOIC

[Gabbro, meta-gabbro and diabase dykes (DOOR)]

[Granite, quartz monzonite and granodiorite (hachrite lake granite) (DAVY)]

APHEBIAN

[Granite, quartz monzonite and granodiorite (LEPO)]

Lithic greywacke to subgreywacke (DOUG)

Conglomerate (CLEM)

Arkose to subgreywacke (DRYG)

Lutite, quartz lutite,dacite and tuff (DICK)

Ferruginic, cummingtite, calc-silicate bands derived from 14 (DRYG)

Undivided 11, 12 and 13 (DRYG)

Dolarite, limestone and other argillite, phyllite (DAVY)

Gabbro sills (DOOR)

Argillite, phyllite, greywacke, some minor dolomite (DRYG)

Quartzite, orthoquartzite (DRYG)

Greywacke-conglomerate, greywacke, protoquartzite (CLEM)

ARCHEAN

Meta-gabbro dykes (MAUD)

Quartz monzonite, granodiorite and granite; massive to foliated (GIRC)

Diorite and gabbro (DORY)

Grey biotite granodiorite gneiss (DUNS)

Ferruginic, minor paraschist (FOG)

Amphibolite, amphibolite gneiss (GOYA)

Greywacke, greywacke-conglomerate, argillite, phyllite, minor tuff (DRYG)

Meta-volcanic rocks (MAC)

Drift-covered areas.....

Geological contact.....

Fault.....

Limit of geological mapping.....

Eskers (direction of flow known).....

Mineral occurrence.....

Legend modified and geology derived for the geochemical map by R.G. Garrett from maps 24-1970, 3-1972 and 6-1972 and G.S.C. Paper 74-54 BY: K.E. Eade

Geological cartography by the Geological Survey of Canada

Base-map at the same scale published by the Mapping and Charting Establishment, M.C.E., 1968

Mean magnetic declination 1977, 19°06.9'E decreasing 3.6' annually. Readings vary from 19°10.2' in the SE corner to 19°04.0' in the NW corner of the map area

Elevation in feet above mean sea-level

Geochemical Symbol and Data Presentation

The concentration of an element at a sample site is graphically represented as one of 15 symbols, if a sample was collected but there is no data available a dot is plotted. The symbols are symmetrically arranged so that they first increase in size, then in number of segments filled in, and finally in number of rings. The two small crosses at the low end of the scale are used to respectively denote concentrations below the analytical detection limit, or, in the data group containing the detection limit. The data are grouped on a semi-logarithmic scale, i.e. 1,2,5,10,20,50,100 etc. Five decades can be spanned and this arbitrary division of the data is consistent throughout Canada wide series of maps constituting the National Geochemical Reconnaissance.

The choice of symbols and the data groups they represent for any specific element is based on the histogram and cumulative frequency plot for the total survey data from one, or more contiguous, open file sheets covered in one field season. The class interval for the histogram is usually one-half of a log cycle (one, then one and a half) and includes the median of the data as defined by the 0.5 (50%) point on the cumulative frequency plot. Some, or all, of the remaining 14 symbols are chosen so as to achieve an appropriate graphical impact. An example of all 15 symbols is given below.

The data groups are based on the total survey data distributions, are unaffected by the variability of user increasing levels of knowledge in bedrock and surficial geology, and other environmental factors. Therefore, the raw data symbol maps are only intended to assist the rapid inspection of the data for gross regional features. To fulfil the needs of a more specific and thorough interpretation, the user must consider the raw data in the light of all the geological data provided in the final findings and any other knowledge available. To assist in the appraisal and modification of the data in terms of the symbol map bedrock geology, a table of summary statistics and proposed threshold values for drainage samples dominantly derived from each mapped bedrock unit, or broad lithologic unit, again for the total survey data, is provided. Histograms and probability plots can also be used along, or in conjunction, with the sample location map and data listing to indicate above threshold samples where they occur on the map. In many instances, the table will also illustrate, more clearly than the map, the dependence of mean geochemical levels on bedrock type. It may often be also observed that the "tail" of the distribution, above the proposed threshold, contains the data for individual map or lithologic units appears to approximate a normal distribution. The proposed thresholds presented are believed to be useful to interpreting the data from a mineral exploration viewpoint. Locations of samples with concentrations in excess of the threshold for the rock unit they appear to be derived from, are highlighted on the map. Such anomalous concentrations can be due to a wide range of geological and environmental factors, but one of these could be the presence of abnormal concentrations of the element in a form of interest to the mineral exploration.

To comprehensively study an area, all available geological, environmental and geochemical data must be used. The final anomalies selected for follow-up action be imposed by constructing new data subsets and deriving local threshold levels based on the most detailed and up-to-date knowledge available.

The term reliability factor and value that appears below the table is an estimate of the reliability of the geochemical map. On the basis of duplicate analyses, 95% of the data should be within the range of the value ÷ or × the factor. If any take is reanalyzed and identical methods of sample preparation and analysis are used the new value will lie between X ÷ RF and X × RF where X is the original value obtained. This factor takes into account variability due to both heterogeneity of the centre-take bottom sediments and sample preparation and analytical causes.
