BIOSTRATIGRAPHIC ZONATION

IOE NUKTAK C-22

SUMMARY AND CONCLUSIONS

The biostratigraphic analysis on IOE Nuktak C-22 includes a palynostratigraphic study by Dr. G. Norris, and a micropaleontological investigation by Dr. W. Braun.

One hundred and thirty two prepared palynology slides and 206 micropaleontology samples were made available by the operator of the well, providing good coverage for both faunal and floral examination. No conventional core material was obtained on this well.

A continuous zonation spanning the interval from Middle-Upper Eocene to Neogene was established utilizing 8 recognizable microflora zones, from total depth (12,600 feet) to near surface.

Microfaunal assemblages are limited to marine, lagoonal and near-shore occurrences in a generally terrestrial-deltaic sequence, and because of sporadic occurrences have limited value for absolute age determination. Assemblages are, however, useful in supporting the palynological zonation, and for correlation between wells.

A zonation summary is as follows.

Summary of Zonation

| Age | Interval | Zonation | |
|---------------------|---------------|--------------------------|---------------------------------------|
| | | Palynology | Micropaleontology |
| Neogene | 0'- 2,370' | NT-1 (30-1110') | Assemblage I (0-950') |
| | | NT-2 (1200-2370') | Assemblage II (950-1900') |
| Oligocene | 2370'- 4,310' | NT-3 (2550-4310') | |
| Middle-Upper Eocene | 4310'-12,600' | NT-4 (4353-5280') | |

PALYNOSTRATIGRAPHIC STUDY

BY

DR. GEOFFREY NORRIS

PALYNOSTRATIGRAPHY

IOE NUKTAK C-22

BY

GEOFFREY NORRIS, PH.D.

INTRODUCTION

This report is the result of palynologic analysis of material supplied by Austin and Cumming Exploration Consultants, Calgary, on the IOE Nuktak C-22 well drilled through putative Cenozoic sediments in the Mackenzie Delta region.

The objectives of the study are to establish a palynologic zonation to facilitate correlation between other wells in the region; to report on environments of deposition and paleoecology of the assemblages where possible; and to determine age relationships of the flora.

Emphasis will be placed on the local palynologic succession in each well, and a zonation will be established principally on the tops of ranges of species (successive disappearance zones of Vella). Palynofloral abundance data are notoriously variable and poorly understood - in part due to their dependence on sedimentation patterns - and impossible to assess meaningfully, other than in a general way, from cuttings samples. Staplin *et al.* (1975) have illustrated selected abundance curves of Neogene and Paleogene miospores from the Delta. Their data suggest a dominance of fungal spores in the lower Paleogene, a rise to dominance of monolete spores and fir pollen over other coniferous pollen in the upper Paleogene, and a change in abundance of bisaccate pollen and other types in the Neogene.

Although this method may have possibilities for crude stratigraphic correlation in the absence of index fossils, it requires heavy investment in time, personnel, statistical methods, and computer hardware and software. All are beyond the resources and time available for the present study. Consequently more effort has been expended in careful taxonomic study and identification of the material and comparative biostratigraphy amongst the wells to achieve a chronostratigraphic zonation based on species of restricted range and often of low abundance. This method is apparently used successfully by several companies operating in the Delta area (Staplin *et al.*, 1975).

Palynologic species are designated by either a published Latin binomial or by a generic name and number, e.g., *Taxodiaceapollenites hiatus*, *Ulmus-1*, *Tricolporopollenites-3*, *Diconodinium-5*. In addition, these names are prefixed by a unique number for convenience of plotting data on paleo-logs, e.g., 1, 320, 373, and M219 respectively for the preceding species. All species are terrestrial spores and pollen except those with a unique number prefixed "M" to indicate microplankton (mostly marine dinoflagellates and acritarchs). A full numerical listing of unique numbers and their corresponding species names is provided in the Appendix. This is a comprehensive list comprising many Mesozoic-Cenozoic palynomorphs common in eastern, western, and arctic Canada. Not all will be referred to in this report.

SUMMARY

One hundred and thirty-two samples from the subject well yielded 95 terrestrial and 37 marine palynomorph species as indicated in Figure 1. Certain species are illustrated in Plates 1-3. Table 1 summarizes zones, ages assignments and depositional environments.

Eight zones are recognized, spanning the Upper Eocene and Oligocene between T.D. and 2370 feet and with Neogene occupying the top 2,000 feet approximately of the subject well. The only clearly defined marine interval occurs between 11,160 feet and 12,600 feet (T.D.).

ZONATIONZone NT-1 (30-1110 feet).

Characterized by the common occurrence of:

- ✓ 2 *Taxodiaceae pollenites hiatus*
- ✓ 7 *Gleicheniidites senonicus*
- ✓ 12 Recycled Carboniferous
- ✓ 42 *Araucariacites australis*
- ✓ 1 *Stereisporites antiquasporites*
- ✓ 5 *Alisporites bilaterialis*
- ✓ 22 *Cyathidites minor*

In addition, the following species occur sporadically:

- ✓ 326 *Pinus-1*
- ✓ 34 *Laevigatosporites ovatus*
- ✓ 16 *Deltoidospora hallei*
- ✓ 54 *Distaltriangulispores perplexus*
- ✓ 239 *Sequoiapollenites paleocenicus*
- ✓ 287 *Alnipollenites-1*
- ✓ 323 *Pterocarya levis*
- ✓ 324 *Carpinus subtriangula*
- ✓ 377 *Ericaceae-1 (probably recycled)*
- ✓ 381 *Psilatricolpites-1*
- ✓ 3 *Classopolis torosus*
- ✓ 4 *Cicatricosisporites hallei*
- ✓ 36 *Lycopodiumsporites reticulumsporites*
- ✓ 25 Recycled Permo-Triassic
- ✓ 390 *Salix-1*
- ✓ 318 *Eucommiidites minor*
- ✓ 26 *Vitreisporites pallidus*
- ✓ 48 *Circulina parva*
- ✓ 20 *Trilobosporites apiverrucatus*
- ✓ 396 *Tiliapollenites-2*
- ✓ 407 *Laevigatosporites-1*
- ✓ 214 *Cirratriradites teter*
- ✓ 229 *Sigmopollis hispidus*

IOE NOKTAK C-22

| DEPTH | ZONES (PALYNOLOGY) | ENVIRONMENT | AGE |

| 6000' | NT-4 5280' | THIN MARINE INTERVALS | MIDDLE & UPPER |
| 8000' | NT-5 7590' | | EOCENE |
| 10,000' | NT-6 8590' | | (POSSIBLY OLIGOCENE IN PART) |
| 12,000' T.D. 12,600' | NT-7 10,980' | NEAR-SHORE MARINE | |
| | NT-8 | | |

TABLE 1

- 236 *Schizosporis reticulatus*
- 10 *Perinopollenites elatoides*
- 284 *Cupuliferoideaepollenites-*
- 19 *Osmundacidites wellmanii*
- 33 *Cyathidites australis*

Some of the above species are recycled from the Paleozoic, Cretaceous, and lower Tertiary. Of particular significance is the presence of 407 *Taevigatosporites-1* and 229 *Sigmopollis hispidus* which are short-ranging Neogene species characterizing this interval. M237 *Svalbardella-1* is the only possible marine palynomorph that is indigenous to this zone.

Zone NT-2 (1200-2370 feet).

Characterized by the common occurrence of:

- 220 *Betulaceaepollenites-1*
- 408 *periporate-1*

Sporadic species include:

- 360 *Alnus trina*
- 46 *Parvisaccites radiatus*
- 9 *Cerebropollenites mesozoicus*
- 45 *Schizosporis parvus*
- 378 *Pluricellaesporites-*
- 6 *Cingutriletes clavus*
- 335 *Costatoperforosporites fistulosus*
- 369 *Cranwellia striata*

All except the first of these sporadic species are probably recycled Cretaceous and Tertiary elements.

Nineteen species of marine microplankton are present in Zone NT-2 but all are recycled Lower and Upper Cretaceous species.

Zone NT-3 (2550-4310 feet).

Characterized by the common occurrence of 395 *Corylus-1* and 371 *Tsuga-1* and the less frequent occurrence of 399 *Castanea-1*.

Occasional marine plankton species occur in this interval as indicated in Figure 3 but all are recycled Cretaceous specimens.

Zone NT-4 (4353-5280 feet).

The following species occur in this zone but none are common except *Ericaceae-1*:

- 214 *Cirratiradites teter*
- 377 *Ericaceae-1*
- 320 *Ulmus-1* (possibly recycled)
- 313 *Trilobosporites purverulentus*

- 411 *Abies*-1
- 409 *Stereisporites*-2
- 410 *Engelhardtia*-1
- 387 *Tricolporopollenites*-6

Ericaceae-1, *Abies*-1, and *Stereisporites*-2 are taken to characterize this zone.

M233 *Horologinella*-1 characterizes this zone and Zone NT-5 below. Although grouped with marine plankton in this study, it is possibly a freshwater algal cyst allied to the desmids.

Apart from recycled Cretaceous microplankton, no other indigenous marine plankton species occur.

Zone NT-5 (5370-7590 feet).

The top of the range of 412 *Lycopodiumsporites*-1 is clearly defined in this zone. In addition, rarer species also characterize the interval:

- 413 *Stereisporites*-3
- 247 *Aquilapollenites attenuatus*
- 50 *Coronatisporites valdensis*
- 373 *Tricolporopollenites*-
- | 31 *Lycopodiumsporites austroclavatidites*
- 414 *Triatriopollenites*-
- 291 *Tricolpites hians*
- 183 *Baculatisporites comaumensis*

Apart from recycled Cretaceous marine microplankton, the only possible indigenous marine type is M242 *Korojonia*-1 near the bottom of Zone NT-5.

Zone NT-6 (7682-8590 feet).

416 *Osmundacidites*-1 has a well-defined range in this zone. In addition, the following also occur but are probably recycled, other than the first:

- 405 *Cicatricosisporites intersectus*
- 415 *Aquilapollenites cf. murus*
- 417 *Contignisporites cf. fornicatus*

No unequivocally indigenous marine plankton species are present in Zone NT-6.

Zone NT-7 (8695-10,980 feet).

Common species characterizing this interval include:

- 419 *tetrad*-1
421 *Leptolepidites*-1

Rarer terrestrial species include:

- 418 *Polyopodiisporites*-1
420 *Laevigatosporites*-2
362 *epiphyllous fungi*
422 *Parviprojectus*-1
402 *Ginkgo*-1
282 *Caryapollenites paleocenicus*
398 *Basopollis*-1
381 *Psilatricolpites*-1
372 *Granatitricolpites*-1

Weak marine influence is indicated 540 feet above the base of Zone NT-7 by the presence of M244 *Astrocyta*-1. Sporadic recycled marine Cretaceous palynomorphs also occur in this zone.

Zone NT-8 (11,160-12,600 feet).

This zone is characterized by the following frequently occurring species:

- 374 *Granatisporites*-1
367 *Azolla*
400 *Pesavis tagluensis*
391 *Striadiporites sanctaebarbarae*

The following species occur more rarely:

- 325 *Aquilapollenites cf. reticulatus*
384 *Retitricolpites*-1
370 *Titiapollenites*-1
24 *Podocarpidites multisimus*
375 *Granatisporites*-2
330 *Pistillipollenites mcgregorii*
392 *Granatisporites cotalis*
30 *Phyllocladidites inchoatus*

A well-defined marine assemblage also characterizes this interval and comprises the following species:

- M244 *Astrocyta*-1
M235 *Diconodinium*-7
M229 *Wetzeliella cf. hampdenensis*
M245 *Cordosphaeridium cf. diktyoplodus*
M246 *Samlandia*-1
M230 *Cannosphaeropsis cf. reticulensis*

PALEOENVIRONMENTS

The only clearly defined marine interval occupies Zone NT-8 between 10,980 feet and 12,600 feet with a possible extension upwards to 10,440 feet based on the occurrence of *Astrocytula*-1 at this horizon. The limited number of marine species and relative abundance and diversity of terrestrial species suggests near-shore conditions of deposition in this interval.

The entire section above the marine interval is terrestrial (with occasional recycled Cretaceous microplankton) apart from the following probably indigenous species at the horizons indicated:

- M237 *Svalbardella*-1 1110 feet.
- M242 *Korojonia*-1 7050 feet.
- M233 *Horologinella*-1 7682-4518 feet.

Svalbardella-1 and *Korojonia*-1 indicate very limited marine incursions at their respective horizons.

The environmental significance of *Horologinella*-1 is less certain. It may be marine but could also be a freshwater algal cyst.

MATURATION

Degree of maturation of palynomorphs in this well ranges from light yellow-dark yellow (1-3) through the upper 8100 feet, yellow-amber (2-4) through the interval 8210-11,700 feet, and dark yellow-brown through the lowermost interval 11,790 to 12,600 (T.D.). (See Figure 1)

CORRELATION

Palynostratigraphic correlations between IOE Nuktak C-22 and Shell Niglintgak H-30 are summarized as follows. The successive disappearance zones are prefixed NI for the Niglintgak well and NT for the Nuktak well.

NT-8:

Zone NT-8 is firmly correlated with Zone NI-4 on the basis of the common occurrence of 400 *Pesavis tagluensis*, 391 *Striadiporites sanctae-barbarae*, 367 *Azolla*, and 325 *Aquilapollenites cf. reticulatus*. The Paleocene-Middle Eocene species 330 *Pistillipollenites mcgregorii* occurs near the NI-5/NI-4 boundary but at the top of NT-8. Little precise correlative significance, however, can be placed on these single occurrences.

The marine phase near the top of NT-8 characterized principally by M229 *Wetzelia cf. hampdenensis*, M244 *Astrocytula*-1, M245 *Cordosphaeridium cf. diktyoplodus*, M246 *Samlandia*-1, and M230 *Cannosphaeropsis cf. reticulensis* correlates with a similar marine assemblage at the top of NI-4.

The marine phase characterizing NI-3 and the lower part of NI-2 is not recognized in the Nuktak well. This phase has the following species, none of which occur in any Nuktak zone:

- M220 *Lejeunia*-1
- M222 *Ceratiopsis*-1
- M223 *Multiplicisphaeridium*-1
- M227 *Cleistosphaeridium*-1
- M226 *Diconodinium*-6
- M225 *Deflandrea*-3

Its time equivalence in the Nuktak well is not certain at present because terrestrial palynomorph correlations in the intervals spanned by NI-2 and NI-3, on the one hand, and NT-7, NT-6, and NT-5 on the other are not clear. Two limiting possibilities exist for the *Lejeunia*-1, *Ceratiopsis*-1, etc. marine phase:

- (i) it directly succeeds the M229 *Wetzelieilla* cf. *hampdenensis*, *Astrocyta*-1, etc. marine phase, correlating with much of upper NT-8, NT-7, NT-6, and possibly some NT-5.
- (ii) it is principally a biofacies controlled by an over-riding ecologic factor such as salinity or depth, and thus essentially synchronous with NT-8.

There is no doubt, however, that the *Lejeunia*-1, etc. marine phase is definitely post-*Pesavis tagluensis*-*Striadiaporites sanctaebarbarae* zone in age; the question remains just how much of the succeeding Nuktak interval correlates with NT-3 and NI-2 or whether there may be a hiatus at this horizon in the Nuktak well.

NT-7 to NT-4:

This thick interval in the Nuktak well is well-characterized by sequential miospore compositional changes but is difficult to correlate with the Niglintgak well, except at the top where *Ericaceae*-1 disappears in both wells and several other species in the Nuktak well.

Several species occurring in the NI-2 and NI-3 interval also occur in the NT-4 to NT-7 interval but none are sufficiently characteristic in their distribution to allow correlation between these two wells. The Nuktak zones NT-5 and NT-6 are based on species not occurring in the Niglintgak well.

The frequent occurrence of 320 *Ulmus*-1 near the NT-5/NT-6 boundary may indicate a correlation with a similar frequent recurrence within NI-3.

Horologinella-1 occupies most of Zones NT-4 and NT-5 but has an apparently lower range in the Niglintgak well. It may be partially facies controlled, if it is an algal - possibly freshwater - cyst. The probable correlative zone in the Niglintgak well (parts of NI-3 or NI-2) is marine.

NT-3:

The presence of 371 *Tsuga*-1 characterizes this zone in the Nuktak well and Zone NI-1 in the Niglintgak well. However, 395 *Corylus*-1 has a lower range in Niglintgak compared with the Nuktak well, as does 399 *Castanea*-1 which also occurs in NT-3 (the latter may be recycled from below). Other long-ranging species occur frequently in both wells in these zones (220 *Betulaceapollenites*-1, 287 *Alnipollenites*-1, 324 *Carpinus subtriangula*) but other species have disparate distributions.

NT-2 to NT-1:

Correlation of these zones with the Niglintgak well is impossible since the probably correlative horizons were not examined in the Niglintgak well.

NT-1 contains 229 *Sigmopollis hispidus* which also occurs in the upper horizons of the Niglintgak well.

AGE RELATIONSHIPS

Age relationships are summarized in Table I and are principally based on correlations with Shell Niglintgak H-30.

The Nuktak well bottoms in Zone NT-8 which is Middle or Upper Eocene.

The Eocene-Oligocene boundary may be taken at the highest occurrence of *Tiliapollenites*, as discussed on page of this report. In the Nuktak well, this genus occurs near the top of Zone NT-4 (up to 4,518 feet), apart from a probable recycled specimen in Zone NT-1. This would place the base of the Oligocene relatively higher in the Nuktak well compared with the Niglintgak well. The correlative Oligocene-Eocene boundary from the Niglintgak well probably occurs in Zone NT-8 of the Nuktak well, thus indicating that the well may bottom in Oligocene. However, this would conflict badly with a Middle Eocene age (at the latest) for the Horizon at 11,610 feet which contains 330 *Pistillipollenites mcgregorii*. In addition, a specimen on the operator's slides from 5626 feet SWC has been circled and annotated "PJ-1" which corresponds presumably with *Parviprojectus PJ-1* of Imperial Oil Ltd. (Staplin et al., 1975). This species is believed to be late Eocene in age by the Imperial staff. The species is badly torn, however, and the present writer could not confirm its presumed triprojectate pollen structure on that specimen alone. It seems more likely that the Eocene-Oligocene boundary occurs near the NT-3/NT-4 boundary. If 422 *Parviprojectus*-1, which occurs as a single specimen at 9270 feet in the subject well, is conspecific with PJ-1, the Middle -Upper Eocene boundary presumably occurs below this and above definite Middle Eocene at 11,610 feet.

The top of the Paleogene is placed at the highest occurrence of *Corylus*-1, *Castanea*-1, and *Tsuga*-1 at the top of NT-3, which correlates with a similar event at the top of NI-1.

FOSSIL APPENDIX

**Numerical Listing of Unique Numbers
and Corresponding Palynomorph Species
Names Common in Eastern, Western, and
Arctic Canada.**

Terrestrial palynomorphs

1. *Stereisporites antiquasporites* (Wilson and Webster) Dettmann
2. *Taxodiaceae pollenites* Hiatus (Potonie) Kremp
3. *Classopollis torosus* (Reissinger) Balme
4. *Cicatricosisporites hallei* Delcourt and Sprumont
5. *Alisporites bilaterialis* Rouse
6. *Cingutriletes clavus* (Balme) Dettmann
7. *Gleicheniidites senonicus* Ross
8. *Cedripites cretaceous* Pocock
9. *Cerebropollenites mesozoicus* (Couper) Nilsson
10. *Perinopollenites elatoides* Couper
11. *Concavissimisporites punctatus* (Delcourt and Sprumont) Brenner
12. Recycled Carboniferous-Devonian spores.
13. *Alisporites grandis* (Cookson) Dettmann
14. *Lycopodiumsporites marginatus* Singh
15. *Cicatricosisporites annulatus* Archangelski and Gamerro
16. *Deltoidospora hallei* Miner
17. *Cicatricosisporites cf. A. exilioides* (Maljavkina) Bolchovitina
18. *Tigrisporites scurrandus* Norris
19. *Osmundacidites wellmanii* Couper
20. *Cicatricosisporites australis* (Cookson) Potonie
21. *Cicatricosisporites hughesi* Dettmann
22. *Cyathidites minor* Couper
23. *Ginkgocycadophytus nitidus* (Balme) de Jersey
24. *Podocarpidites multisimus* (Bolchovitina) Pocock
25. Recycled Permo-Triassic pollen.
26. *Vitreisporites pallidus* (Reissinger) Potonie
27. *Ephedripites multicostatus* Brenner
28. *Neoraistrickia robusta* Brenner
29. *Cicatricosisporites augustus* Singh
30. *Phyllocladidites inchoatus* (Pierce) Norris
31. *Lycopodiumsporites austroclavatidites* (Cookson) Potonie

MICROPALEONTOLOGICAL STUDY

BY

DR. W. BRAUN

SUMMARY OF MICROPALAEONTOLOGICAL STUDY

General Remarks

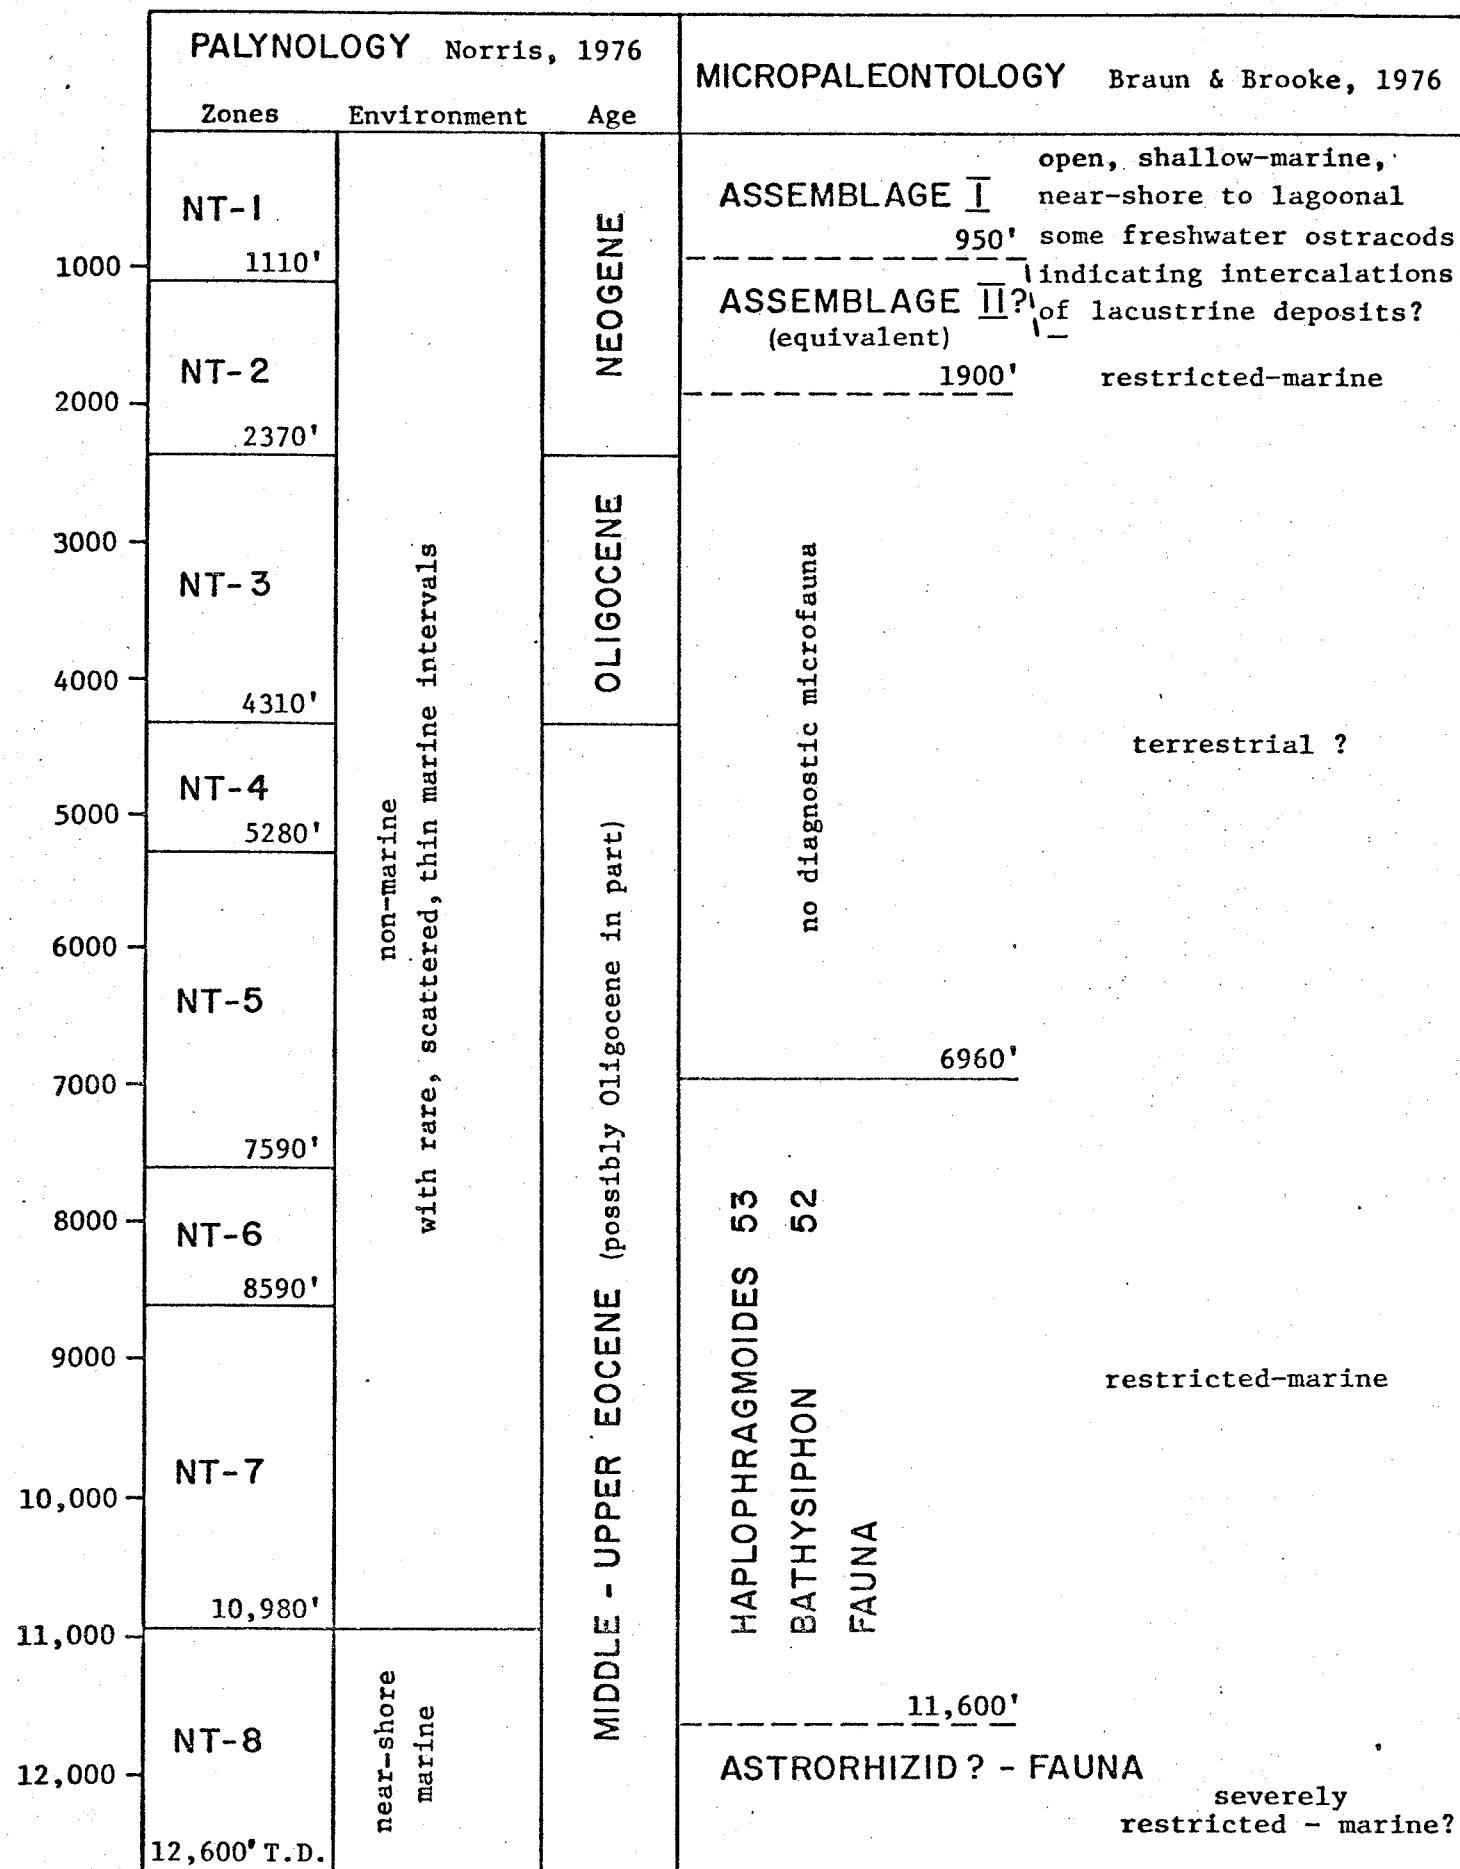

206 slides were available for micropaleontological study. The uppermost 1050 feet of the section were covered by samples spaced about 100' apart; from this level to about 12,500', spacing was either 50' or 60' apart, narrowing to 30-foot intervals in the lowermost 120' of the borehole.

All microfossils that could be identified, including certain characteristic fragments were provided with species numbers, and their sequence is shown on the chart. Whenever possible, the forms were identified to generic rank or as close as possible, but no attempt has been made to search the "international literature for identical or closely related forms. Only a thorough paleontological study, based on extensive collections would do justice to such an attempt. It would require also an intimate knowledge of the paleontological and stratigraphical problems, and bias, contained "in between the lines" in any published account. There is no obvious similarity to any fauna published from North America, except for the fauna of the youngest and pre-Recent assemblage in the uppermost part of this borehole. Faunas from Siberia, however, show closer relationship but literature search is made difficult for many reasons. So the microfauna of the Delta region has to be evaluated on its own merits first and for the time being, and there is nothing wrong with this procedure provided certain steps are taken in the right order.

One of the most critical requirements in any paleontological study is consistency in identification, and this consistency is best achieved by giving an adequate, visual impression of the taxa recovered, and document in detail their occurrences and distribution in individual distribution charts, summary range-charts, etc. Charts are usually given in reports or publications, but rarely are good photographs included. For this reason, emphasis was placed on photographic documentation of the key species, and also of many of the background fauna. Such documentation, it is hoped, will serve to unify the many existing number codes used by other investigators in speciation and which are at times hard to translate into ones own work, and which make even detailed studies rather confusing to interpret.

The micropaleontological data are plotted from "top to bottom", a standard procedure in subsurface studies. First occurrences are used to delineate the

IOE NUKTAK C-22

upper boundary of a faunal complex although, in reality, these are last occurrences. Lower boundaries are hard to define without the results from core samples, but the "trailing" of specimens through the Nuktuk borehole seem to be not too excessive.

The usefulness as time indicators of the microfauna recovered is very limited, in fact it is non-existent. The lack of planktonic forms, the endemic nature of many of the benthonic forms discovered, the sporadic and erratic occurrences of the fauna being restricted essentially to a few more "marinish" horizons in an essentially terrestrial-deltaic sequence make it extremely hazardous to tie the microfauna into a proper time framework. The microfaunal assemblages are for this reason simply traced by number or name, without any age connotation attached. They can be used as such readily in correlating from one borehole to the other, provided the fauna, or part of it, is the same. Any references to stage and ages that are used are those adopted from palynological studies, and the micropaleontological data are summarized in a table with the palynological ones shown alongside.

Microfaunal Assemblages

Two major microfaunal complexes and two minor assemblages were encountered although the section was considered to be mainly of non-marine origin with rare, scattered, thin marine intervals by Norris, and based on palynological evidence.

ASSEMBLAGE I

The widespread and characteristic Assemblage I - Fauna was encountered from about 90' to 950' of the uppermost section of the borehole. Elphidiid and miliolid Foraminifera, and a few shallow-water, marine ostracods are prevailing in the 90 to 690 - foot interval; freshwater ostracods replace this fauna down to the 950-foot level. Clearly then, the fauna seems to be of shallow-marine origin in the upper, and of freshwater origin in the lower part of this assemblage interval. In other wells, the freshwater and marine components are more mixed, indicating a more complex pattern of intergrading facies.

Miliolid Foraminifera and heavily sculptured cythereid ostracods, with typically well-developed hinges are characteristic of open-marine, shallow and near-shore environments, whereas the elphidiids occur also in lagoons and embayments. Characteristic for these assemblages, including Assemblage I, is the dominance of calcareous forms and the scarcity, if not absence of the agglutinated Foraminifera indicating that freshwater influences and restrictive conditions

were minimal to absent.

In contrast, the freshwater ostracods with such typical representatives as the genera Candonia, Iliocypris and Limnocythere are unmistakable indicators of lacustrine environments, and a major shift in the environment of deposition must have taken place at about the 690-foot mark.

Assemblage I is referred to as the "Sigmopollis-Ostracod-Elphidium-Assemblage" in Staplin's (et al.) summary, and is shown on their correlation chart to occupy the highest part of the Neogene section and zone T4 c. in Taglu C-42. Chamney shows a relatively thick Pleistocene to Recent section (unit 1 and 2) in the Reindeer D-27 borehole which contains ostracods and chara. This section seems to be particularly thick in the Tuk F-18 well and was found in many other boreholes according to his cross-section. Norris' NT1 -Zone of Neogene age spans about the same sample interval as does Assemblage I.

ASSEMBLAGE II (? equivalent)

A few badly preserved specimens of some Foraminiferal species and a few ostracods are spread erratically over the 950 to 1900-foot interval. Agglutinated Foraminifera dominate in this "shadow-fauna" indicating restricted to severely restricted marine conditions. Some of these forms, if not all, may be even re-worked.

For these reasons, the fauna cannot be exactly placed in its proper stratigraphic position. It may be a restricted-marine equivalent of Assemblage I, or it may be such an equivalent of the underlying Assemblage II, as is suggested tentatively and until more precise age dates are available.

The Assemblage II-fauna is commonly composed of many rotaliid and miliolid Foraminifera, without the elphidiids and marine ostracods; as such it would indicate that it developed "seaward" of the Assemblage I - fauna.

Assemblage II is equivalent to Staplin's (et al.) Asterigerina 501-Fauna that marks the lower part of their Neogene section and the upper part of their T4 a - Zone in the Taglu C-42 borehole. Norris' NT 2-Zone of Neogene age spans the same interval at Nuktuk as does the "undiagnostic or shadow fauna".

HAPLOPHRAGMOIDES 53 and BATHYSIPHON 153 - FAUNA

This assemblage is dominated by two abundant and quite characteristic species groups: the Haplophragmoides 53 and 154, and the Bathysiphon 52 and 153 group.

As the study proceeded it was found necessary to split the original species in order to accomodate some distinctive variations.

This fauna appears at the 6960' level at Nuktuk and continues nearly uninterrupted to about 11,600 feet of the section. Both groups are abundantly represented. How much of contamination is involved cannot be ascertained without the results from core samples, but it is assumed that this fauna covers a rather long interval, and indicating that restricted, but restricted-marine conditions prevailed, as may have been present in the landward part of an estuarine setting where freshwater influences were strong and marine influences relatively weak.

There is no diagnostic fauna above or below this interval to place it in its proper stratigraphic framework, and it has to stand on its own for this reason. Norris gives a Middle and Upper Eocene, possible Oligocene (in part) age assignment for this interval, spanning the lower part of his NT 9 - Zone and the upper part of his NT 6 to 7 sequence. Such evidence, therefore, would place this fauna relatively high in the Tertiary succession.

Undiagnostic Fauna

The base of the section, from 11,600' to 12,600' T.D. contains obscure but nevertheless characteristic fragments which are questionably referred to a very primitive foraminiferal group, the Astrorhizidae, but which might be of any other origin. These fragments are associated also with many plant remains. A severely restricted-marine environment is suggested, but cannot be proven without finding any more diagnostic, associated faunal elements.
