Abstract

This report announces the availability of approximately 2300 km of seismic reflection profiles in the Strait of Georgia, and provides a subset of that data. The survey extends from Texada Island in British Columbia, Canada to Lummi Island in Washington, U.S.A. These geophysical records are relevant to geological, environmental and marine geotechnical investigations of this populous marine basin on the Canada-U.S.A. border. These data were acquired in 1982 and 1983 by the Geological Survey of Canada in a series of cruises on board the CSS Vector and the CFAV Endeavour. They provide one second reflection records over portions of the Comox, Nanaimo and Whatcom basins. Figure 1, a 1:250,000 scale program map shows the approximate coverage of the survey. Trackline locations are shown with respect to the coastline of the Strait of Georgia. Table 1 includes line designations with start and end positions for all of the lines. For convenience in ordering individual lines, or portions thereof, lines are labelled at their starting ends, with tic marks corresponding to navigational fixes for hourly intervals. The lines shown in Figures 2 and 3 are highlighted on Figure 1. A listing of 5-minute navigation fixes for those lines is given in Table 2. Navigation for the lines is by Loran-C; precise to about 50 m in the Strait. These CSP lines were collected by firing on time. For a ship speed of 4 knots, the typical shot spacing is about 2m. For most lines, the seismic system consisted of two small airguns fired simultaneously (Bolt:PAR 1 and 5 cu.in.), a short single channel hydrophone array (17.5 m active length, 50 Benthos Aquadyne AQ-1 hydrophones with a 35 cm interelement spacing and a pre-amp with a constant gain of X1000) a Kronhite filter and an EPC recorder. Data were recorded with pre-amp and Kronhite filter settings of 80 hz - out. The typical band width is 80 to 500 hz, permitting resolution of 2 to 10 m layering in the modern muds, glacial and interglacial sediments.

Eleven example seismic lines cross prominent subsurface physiographic features and demonstrate the average data quality. Most lines are oriented NE-SW, across strike for many of the glacial and older geological structures. The vertical scale in Figures 2 and 3 is given in two way reflection time and as equivalent water depth (at a water velocity of 1483 m/s). The horizontal scale is in ship-track time for an average vertical exaggeration of about x21. The one second sweep usually permits penetration through the entire unconsolidated Quaternary section, with acoustic basement identical to bedrock. Figure 2 shows sections from the northern half of the survey area between Hornby Island and Porlier Pass. It contains 5 cross-strait lines and 1 basinal tie line which detail portions of the southernmost Comox Basin and Ballenas Basin with their hemipelagic fill, the older drumlinized glacial deposits of McCall and Halibut Banks, and the foreslope of the Fraser Delta with older "core" deposits and examples of recent slumping. Figure 3 shows sections from the southern half of the survey area from Active Pass to Lummi Island, approximately 2/3 of which is in U.S. waters. It contains 4 cross-strait lines (the southernmost of which is in two sections) and 1 basinal tie line which detail portions of Roberts Swell, Boundary Basin, and Alden Bank. Strong bottom reflections from the older Quaternary deposits, and a thinner Quaternary interval, characterize the southern section. It lacks the veneer of acoustically transparent modern muds derived from the Fraser River. As a corollary to the thinner package of unconsolidated sediments, the lines of the southern section show more underlying bedrock geology with dipping reflectors in the Tertiary sedimentary strata of the Whatcom Basin.
