## INTRODUCTION

As part of the Canada-New Brunswick Mineral Development Agreement (1984-89), a Quaternary geology and till geochemistry project was initiated in Northern and Central New Brunswick in June of 1985. The objectives of this project are:

1. to define strategy and methodology of sampling and geochemical analysis for mineral exploration in drift covered areas of Central and Northern New Brunswick;
2. to study the regional drift geochemistry, near-surface glacial stratigraphy and sedimentology, over Miramichi and Chaleur Bay-Tobique zones;
3. to study at a local scale, the stratigraphy and geochronology of the glacial deposits in order to relate the depositional sequence to the detailed geochemical mapping of till in areas of known mineralization;
4. Reconnaissance mapping of Northern New Brunswick with special emphasis on dispersal models and relationships of late glacial reversal of ice flow to other glacial events.

The synthesis of all the information collected during this study will be published at a later date under the form of a GSC Memoir or Paper. The raw geochemical data are released in the form of Open Files. These include the progress and final reports of all available geochemical data collected during the regional sampling programs. For the sake of readability, data are released in three regional reports. They cover the Northern, Central, and Southern part of the Miramichi Zone and its vicinity. The geochemical and lithological data collected under the drilling and trenching programs carried in 1986 through 1987 will be the subject of separate Open Files.

This Open File releases the geochemical results available for the Northern part of the Miramichi Zone, as of Spring 1988. It includes the data obtained from samples collected between June 1985 and October 1986, in an area defined by latitudes  $47^{\circ}15'$  and  $48^{\circ}05'$ , and longitudes  $65^{\circ}30'$  and  $67^{\circ}00'$ . Most of the sampling was carried over the California Lake, Charlo, Nepisiguit Falls, Bathurst, and Pointe-Verte NTS map sheets (21O8, 21O16, 21P5, 21P12, 21P13).

## BEDROCK GEOLOGY

Three of the Pre-Carboniferous tectonostratigraphic zones defined by Ruitenberg et al. (1977) extend into the area:

- (1) the Miramichi Zone, consisting of Ordovician and perhaps older, metamorphosed and highly deformed volcanic, sedimentary and intrusive rocks (Tetagouche Group);
- (2) the Elmtree Zone, an uplifted block of deformed and metamorphic gabbro, amphibolite, peridotites, basalts, greywackes and slates of the Ordovician Elmtree and Fournier Groups;
- (3) the Tobique-Chaleur Zone, an assemblage of Ordovician, Silurian and Devonian sedimentary, volcanic and intrusive rocks. Numerous Devonian granitic stocks intrude the series. The pre-Carboniferous rocks are bounded by major faults.

In the Elmtree area, a basement complex of folded Ordovician-Silurian and Devonian sedimentary rocks is intruded by mafic and felsic rocks (e.g. the Antinouri Granite). Rocks of the Silurian Chaleur Group are in faulted contact with the southern edge of the Elmtree Zone at the Elmtree Break. Gold occurrences have been documented at Alcida, now under study by Lacana Mining Co. There, the gold is present in an altered Devonian gabbro and in sulphide veins cutting through the sedimentary rocks. Gold occurs as free grains ( $10 \mu\text{m}$ ) in silicate gangue, attached to pyrrhotite or pyrite, or in fractures cutting these minerals (Watson, G., pers. comm., 1987). Lacana reported gold analyses of drill core up to 21 ppm Au.

The Upper Nepisiguit River drains the zone of occurrence one of the major sulphide bodies known as the Bathurst Mining Camp. The area is underlain by the rocks of the Tetagouche Group, divided into five lithologic units: two metasedimentary, two felsic metavolcanic in which are contained the ore bodies, and one mafic metavolcanic (Skinner, 1974). Gold occurrences are scarce in the area and related to gossan material, some of which was mined for gold extraction (e.g. Heath Steele Mine).

#### QUATERNARY GEOLOGY

The Quaternary geology of New Brunswick has been recently synthesized by Rampton et al. (1984) and updated in Pronk and Lamothe (1988).

A summary of the flow patterns and geomorphology of northern New Brunswick is shown in figure 1. The stratigraphic sequence seems to record a unique depositional event. However, sub-till non-glacial sediments have been recovered in boreholes drilled along the coastal area, close to Charlo. Their sedimentologic study is still under way, but, so far, only one till sheet, hence, one depositional event, has been observed in the area.

The erosional record is more complex. The oldest ice flow was southeastward, and it is only documented in a few localities. The most intense iceflow recorded is from west to east (ice flow 2, in Fig. 1).

A subsequent northeastward flow into Chaleur Bay is recorded by striae and till fabrics. A late stage northward flow has been reported by Pronk and Lamothe (1988) in the central part of the area (Tetagouche Lake-Upsalquitch Forks). In the coastal area, bedrock exposures record clearly a late southward ice movement (Gauthier, 1982, 1983; Rampton et al., 1984), as ice flowing out of Chaleur Bay impinged on the coast. The implication of this late ice flow for the Quaternary history of the area is not clear at the moment but no significant glacial transport seems to be associated with it.

In the area, till is generally thin, less than 2 m thick on crests and plateaus, but tends to be thicker in the valleys. Thicknesses of 10m or more have been encountered in boreholes, east of the Brunswick #6 open pit mine. From pebble lithology studies (Pronk and Lamothe, 1988; Gagnon, 1987), it is concluded that till is mostly locally derived and that the bulk of the material is transported in an east to east-northeast direction over distances ranging between a few hundred meters to several kilometers.

However, these conclusions should not be applied to the southern part of the area (California Lake and Nepisiguit Falls), since the analysis of pebble lithologies is incomplete. There, the erosional northeastward phase might have controlled more strongly the transport of the glacial debris.

Marine waters transgressed into Chaleur Bay from east (13.2 ka) to west (12.2 ka)

simultaneously with ice retreat (Rampton et al., 1984). During this retreat, the "Restigouche Kame" and "Elmtree Interlobate" morainic systems were formed as a series of shoreline parallel, nested, pitted deltas, intimately associated with fossiliferous offshore marine sediments (Bobrowsky et al., 1987). The glacial retreat involved deltaic accretion and marine overlap up to 114 m (asl). This explains the low sampling density close to the coast.

## TILL GEOCHEMISTRY

This project covers the entire Miramichi Zone. Sampling was initially carried out along roadside and natural exposures. In areas of limited access, traverses were undertaken to increase the sample density to 1 sample per 10 km<sup>2</sup>. Geochemical analysis of approximately half of the collected samples were available at the time of writing. Sample locations are shown on Plate I with UTM coordinates listed in Table I.

Two grain-size fractions were analyzed for each till sample collected during the regional survey.

- (1) The clay-sized fraction (<2 µm) was analyzed for Pb, Zn, Cu, Ni, Cd, As, Fe, Mn, Cr, Mo, F, Sn, W, Hg, and U. The logic for analyzing this fraction has been discussed by Shilts (1984) who showed that most of the base-metals will be concentrated in the fine fraction of the till (see also, Lamothe, 1986).
- (2) The clay plus silt fraction (63 µm) was analyzed by neutron activation for 33 elements. The most significant are As, Au, Sb, U, and Th. Detection limits, methods of analysis, and reproducibility data are described in Table II.

The geochemical data are listed in Tables III to VI. The geochemical distribution of zinc (Zn), arsenic (As), antimony (Sb), and gold (Au) in till are shown on Plates II, III, and IV where the data are contoured by the APPMAP program of the Geological Survey of Canada. Plates V and VI show gold abundance in the <63 µm fraction of till in the Pointe-Verte-Bathurst and Heath Steele area. Location of trenches T3 to T7 as well as shallow drill-holes D1 to D27 are also indicated on these plates. The geochemical results for these samples are listed in Tables VI and VII.

A complete discussion about the interpretation of the geochemistry will be published when all geochemical results become available. However, because of the recent interest in gold exploration in New Brunswick, the following is a brief discussion of the geochemistry of Ag in the till.

Three large till samples were collected over the Alcida showing at the discovery zone. Partitioning results are displayed in Figure 2 and indicate that medium to coarse silt fraction of till is the principal gold carrier. (The reader is referred to Gagnon 1987 for an in-depth discussion of these results). While high values are found in the clay fraction (up to 2340 ppb Au; not shown here) it seems that the gold is mostly present in 8 to 63 µm average grains. The ore samples after being crushed showed the same geochemical trend (Gagnon, 1987; Lamothe and Gagnon, 1987). Investigation of the sand-sized heavy mineral fraction failed to yield visible gold grains, which seems to indicate that:

- (1) most native gold grains will be found in the fine silt fraction (< 10 µm), as observed in the bedrock and that,

- (2) the gold in coarser silt grains is probably tied to some sulphide mineral. A similar trend is found for Sb and As.

There is a strong correlation between Au and Sb at the Alcida deposit however this correlation is not apparent in the regional survey results. It is believed this might be partly due to the lack of reproducibility for Au in the observed range (< 25 ppb). The nugget effect (or particle-sparsity effect) is suspected to cause the poor reproducibility in the gold analyses that are available so far (Fig. 3). It should be borne in mind that, given the gold level in the samples and the weight of the split used for the analysis (10g), the probability for that split, to contain one particle of gold is very low. It is probable that insufficient particles per sample from the split are available to obtain reliable analytical results this is principally a function of the small size of the samples (1kg) collected during the regional survey.

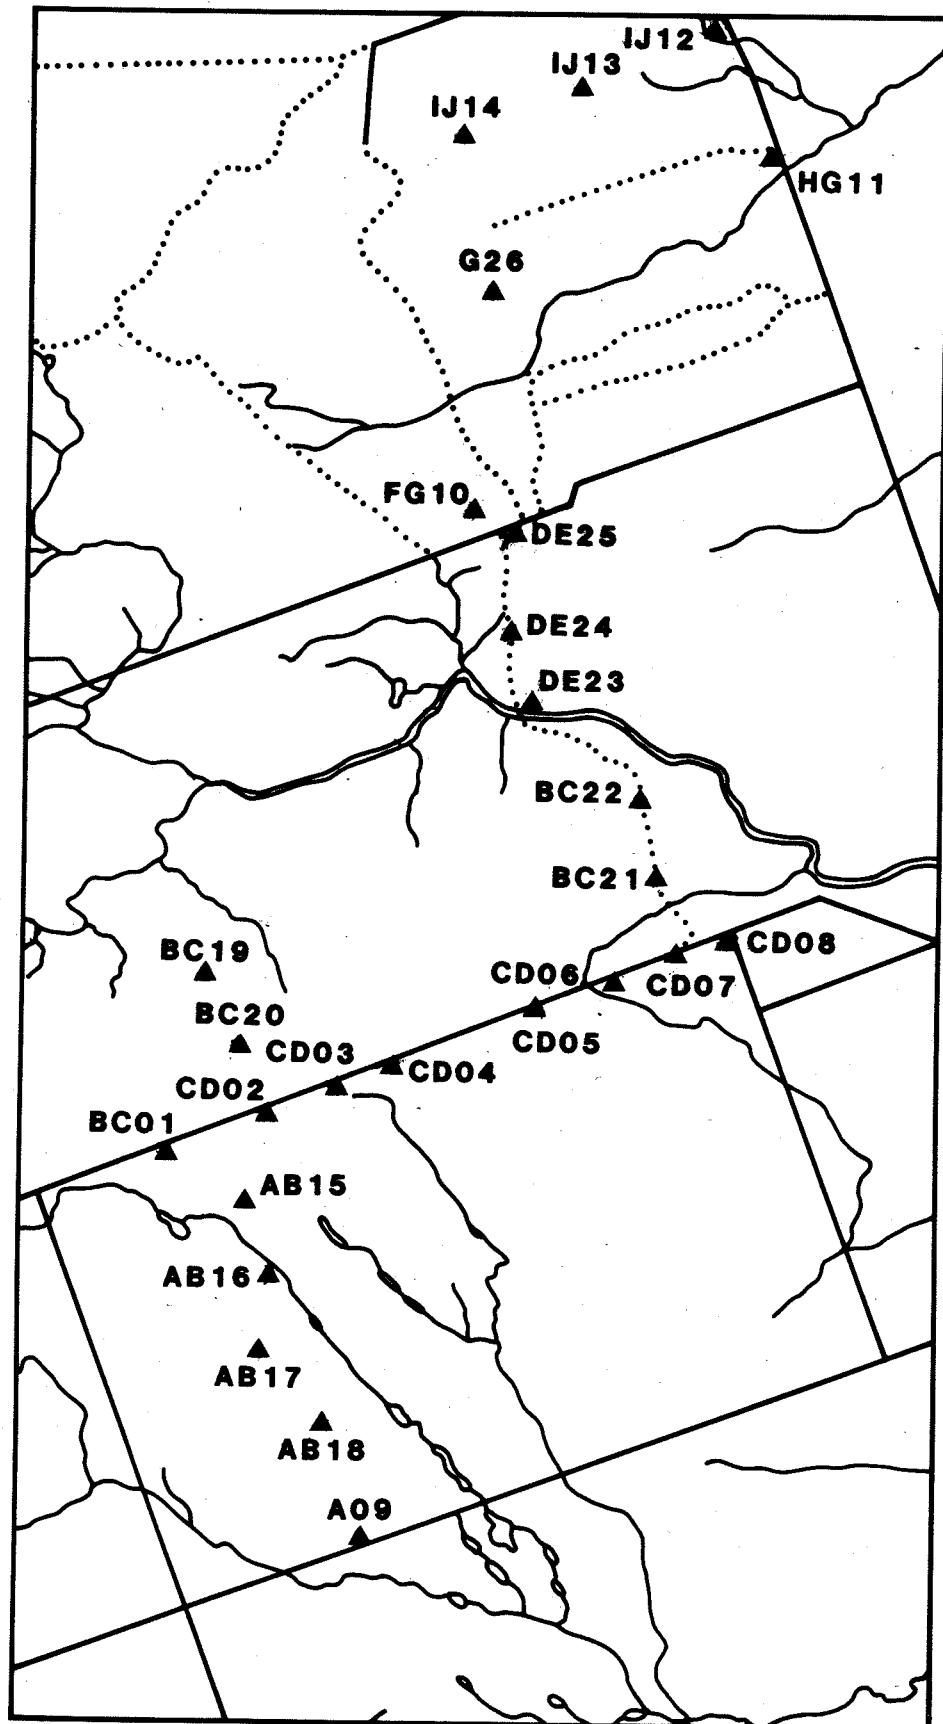

To illustrate the low reliability of the gold results, one needs only to know that the highest Au value measured in this area was 81 ppb Au (Sample 86LFA 5573) on a duplicate sample which failed to yield any gold originally. For these reasons, the gold data are not contoured and caution must be exercised in the interpretation of this data.

Plate IV shows the regional distribution of Sb in till, expressed in percentiles. The triangles indicate the location of the samples. Solid triangles identify samples which returned detectable gold. The contoured Sb data displays elevated values over the massive sulphides particularly at Heath Steele. The contour trends closely follow the Elmtree Break, one of the major exploration targets in Northern New Brunswick. This suggests that the correlation between Sb and Au observed over the mineralized site at Alcida might have a regional significance. Therefore, Sb abundance in till could be used as a pathfinder for gold in Northern New Brunswick. Since the reproducibility for this element is fully satisfactory, it could be concluded that geochemical surveys should emphasize the use of gold pathfinders to define primary areas of economic interest. After such areas have been delineated, detailed surveys could focus on gold itself, by collecting much larger samples in order to reduce the particle-sparsity effect as suggested by Harris (1982).

TABLE II A

&lt;63 µm Fraction

Element	Method	Detection Limit	
As	Arsenic	Neutron Activation	0.5 ppm
Au	Gold	Neutron Activation	2.0 ppb
Co	Cobalt	Neutron Activation	5.0 ppm
Cr	Chromium	Neutron Activation	20.0 ppm
Fe	Iron	Neutron Activation	0.2 pct
Hg	Mercury	Atomic Absorption	5.0 ppb
Mo	Molybdenum	Neutron Activation	1.0 ppm
Ni	Nickel	Neutron Activation	20.0 ppm
Sb	Antimony	Neutron Activation	0.1 ppm
Th	Thorium	Neutron Activation	0.2 ppm
U	Uranium	Neutron Activation	0.2 ppm
W	Tungsten	Neutron Activation	1.0 ppm
Zn	Zinc	Neutron Activation	100.0 ppm

&lt;2 µm Fraction

As	Arsenic	Colourimetric	2.0 ppm
Co	Cobalt	Atomic Absorption	1.0 ppm
Cr	Chromium	Atomic Absorption	2.0 ppm
Cu	Copper	Atomic Absorption	1.0 ppm
F	Fluorine	Specific Ion	20.0 ppm
Fe	Iron	Atomic Absorption	0.1 pct
Hg	Mercury	Atomic Absorption	5.0 ppb
Mn	Manganese	Atomic Absorption	1.0 ppm
Mo	Molybdenum	Atomic Absorption	1.0 ppm
Ni	Nickel	Atomic Absorption	2.0 ppm
Pb	Lead	Atomic Absorption	2.0 ppm
Sn	Tin	X-Ray Fluorescence	1.0 ppm
U	Uranium	Fluorometric	0.1 ppm
W	Tungsten	Colourimetric	2.0 ppm
Zn	Zinc	Atomic Absorption	1.0 ppm

## NOTES TABLES III TO VI

1)-0= not analyzed

2) O= OBSERVATION

3) values lower than detection limit indicated as half the detection limit

e.g.= Au=1ppb

means Au&lt;2ppb

1,2= Bondar-Clegg

10,11,12= Chemex
