BIOSTRATIGRAPHY AND MATURATION STUDIES
OF THE SCOTIAN SHELF

- PART 5 -

- FINAL REPORT -

INTRODUCTION

This is the last in a series of five reports detailing the palynology, micropaleontology, kerogen and fluorescence analysis from four wells on the Scotian shelf. The first chapter will deal with the general stratigraphy of the studied area and where the wells studied fit within the general stratigraphic framework. Chapter two discusses the palynological and micropaleontological results in the four wells. An attempt has been made to apply the GSC micropaleontological zonation to this study, the results of which are presented in this final report.

Appendix A of this report (under separate cover) contains a complete list of samples examined for palynology and the fossils found therein. Species cards, with at least one photograph of each palynomorph used in this study are presented in a large file box labelled Appendix B. A complete list of all photographs taken during this study is supplied as Appendix C. Appendix D contains the completed micropaleontological worksheets (under separate cover), and Appendix E is a list of all micropaleontological taxa which have been stained and mounted for curation. Appendix F is a composite rangechart of palynomorphs used during this study.

CHAPTER 1

STRATIGRAPHY

INTRODUCTION:

This report presents the results of palynological and micropaleontological analysis of the following four wells: Evangeline H-98, Alma F-67, Chebucto K-90 and Sambro I-29. The locations of the four wells are presented as Figure 1.

The formation boundaries used in the following discussion are those provided by the GSC and were taken directly from either the original well history report or the COGLA schedule of wells. The logs and lithological information were not provided and no attempt has been made emend the formation boundaries.

The palynological zonal names used in this report are those used Williams 1975, Bujak and Williams 1977, Williams and Bujak 1977 and Barss et al. 1979. The zonation is summarized in Figure 2, taken from Barss et al. 1979. The micropaleontological zonation is adapted from Ascoli 1986, with each zone given a numerical designation to facilitate drafting (Table 1). Ascoli's zonation is reproduced here as Figure 3.

FIGURE 2. PALYNOLOGICAL ZONATION

Since cuttings samples predominate, the highest occurrence of species (excluding reworking) in the well is the primary basis for delineation of ages or zones. Each age is generally defined at the highest sample in which the marker species of that age or zone occur. Because of the method of sampling, i.e., a 10m composite sample approximately every 30m, there are 20m gaps between the base of one interval and the top of the next. All ages or zones are taken from the highest occurrence of the marker species for that zone or age to the highest occurrence of the marker species for the next zone or age, down hole.

THE EURYDICE FORMATION:

The type section of the Eurydice formation is found between 7850'-9748' (TD) in the Shell Eurydice P-36 well. Palynological dating by Barss et al., 1979 indicates that this section is Rhaetian to Lower Liassic (probably Hettangian). Of the four wells examined in the current study, only Union et al. Sambro I-29 is believed to have penetrated the Eurydice Formation. According to the COGLA schedule of wells the Eurydice Formation was penetrated at 4886' and the well TD within the Eurydice at 10,071'. The upper portion of the formation, between 4886' and 5280' is within the Hauterivian to Aptian undifferentiated interval dated by micropaleontology. Palynological samples were undiagnostic Early Cretaceous between 4040' and 5780'. No samples were provided between 5780' and 9860'. A single sample, composited from the 9860-10070' interval, at the bottom of the well contains two Late Jurassic palynomorphs. These data suggest that the interval referred to as "Eurydice Formation" in the COGLA schedule of wells does not correlate with the type section and another name should be applied to these strata.

VERRILL CANYON FORMATION:

The Verrill Canyon Formation is a facies equivalent, not only of the Abenaki and MicMac Formations but also of the Lower Cretaceous Missisauga Formation. Since the shaly facies of all of these formations are lithologically similar, they were grouped together by McIver into one formation. The type section of the Verrill Canyon Formation is in the Shell Oneida O-25 well between 8,281' and 9,461'. According to Barss et al. 1979, the age of the interval includes the very top of the Berriasian-Valanginian undifferentiated, the *C. elegantulum* Zone (Hauterivian, 9430-8890'), the *A. anaphrissa* Zone (Barremian, 8890-8410') and the lower part of the *S. perlucida-S. schindewolfii* Zone (Aptian, 8353-7000').

The well history report indicates that the Verrill Canyon Formation was penetrated in Husky-Bow Valley et al. Evangeline H-98 (3890m) and Shell PCI et al Alma F-67 (3157m). In Evangeline the base of the Verrill Canyon, from TD to 4780m is barren of microfossils and the barren interval is overlain by a thick interval (4760-3940m) containing Early Cretaceous fossils which are too long ranging for zonation. The top fifty meters of the formation is within the section dated Early Barremian.

In Alma F-67 the bottom sample at 4935m is within the Verrill Canyon Formation and is Kimmeridgian/Tithonian undifferentiated to 4180m where it is overlain by Tithonian to 4020m. The Jurassic is conformably overlain by a sequence of Valanginian - Berriasian from 4000 to 3510m (*P. neocomica* Zone, 3670-3510m), Hauterivian from 3490-3270m (*C. elegantulum* Zone) and by the earliest part of the Barremian from 3250-2940m (formation top at 3157m).

THE MISSISAUGA FORMATION:

By definition, the Lower Cretaceous Missisauga Formation is dominantly a sandstone sequence occurring as thick, massive sand units in the Central Scotian Shelf Basin region. The type section of the Missisauga Formation updip facies is in the Shell Missisauga H-54 well between 11,606' and 7921'. The *P. neocomica* Zone (Berriasian-Valanginian, 11,533-10,179'), *C. elegantulum* Zone (Hauterivian, 9885-8780') and the *A. anaphrissa* Zone (Barremian, 8720-8048') were defined within the type section by Barss et al. 1979.

The type section of the Missisauga Formation downdip facies is in Shell Cree E-35 between 12,303' and 8473'. Barss et al. 1979, report an almost identical zonation from this facies with the *P. neocomica* Zone (Berriasian-Valanginian) from 12,380' to 10,050', the *C. elegantulum* Zone (Hauterivian) from 9980' to 9480' and the *A. anaphrissa* Zone (Barremian) from 9435' to 8550'. The uppermost seven feet of this facies are within the *S. perlucida* - *S. schindewolfii* Zone which occurs between 8480' and 7530'.

In Chebucto K-90 the Missisauga Fm. is seen from TD to 3424m and contains the Hauterivian *C. elegantulum* Zone between 5234m and 5180m. The remainder of the formation is within the Barremian *A. anaphrissa* Zone.

The Missisauga Formation is present in Alma F-67 between 3157m and 2847m. The Barremian *A. anaphrissa* Zone is present from the base of the formation to 2940m where the Barremian is unconformably overlain by the Aptian *S. schindewolfii* Zone. The formation top is within this zone.

The Missisauga Formation is present between 4886' and 3620' in Sambro I-29. Palynomorphs are not diagnostic within most of

this sequence but the foraminifera date the formation as Hauterivian to Aptian. The top three hundred meters of the formation are dated as Barremian by palynology, but no zonation is given due to the paucity of fossils.

In Evangeline H-98 the Missisauga equivalent Verrill Canyon is present, as discussed above.

THE NASKAPI SHALE:

According to McIver, 1972, the Naskapi Shale is a unit approximately 500-600 feet thick, separating the very sandy Missisauga Formation below, from the moderately sandy, silty Logan Canyon Formation above. Depending on its position on the shelf, the Naskapi interval contains variable amounts of sand. The Naskapi shale is thought to be present and well developed in the Naskapi N-30 well, but due to the uncertainty of the correlations and the relationship with the adjacent formations, the type section was chosen in the Shell Cree E-35 well between 8456' and 7886'. The entire type section is within the Aptian *S. perlucida* - *S. schindewolfii* Zone. Jansa and Wade, 1975, reduced the status of the Naskapi Formation to the level of Member, within the Logan Canyon Formation.

The Naskapi Shale is present within the Aptian interval in Alma F-67 (2847-2544m). However, it is within the Barremian in Chebucto K-90 (3424-3318m) and Evangeline H-98 (3890-3388m). In Sambro I-29 all but the upper 121' of the shale are within the Barremian, the top is Aptian.

THE LOGAN CANYON FORMATION:

The Logan Canyon Formation is a very thick sequence of alternating sandstones and shales overlying the Naskapi Shale, or, where the Naskapi interval is too sandy to be recognized, the Logan Canyon overlies the massive sands of the Missisauga Formation. The type section of the Logan Canyon Formation is in the Shell Cree E-35 well between 7903' and 4883'. According to Barss et al. 1979, the lower 373' of the formation are within the Aptian *S. perlucida* - *S. schindewolfii* Zone. This is conformably overlain by the Albian *C. cf. C. vestitum* - *E. minor* Zone from 7470' to 5360'. The formation tops within the Cenomanian *K. williamsii* (=*C. polypes*) Zone.

The Logan Canyon Formation is present in Alma F-67 between 2544m and 1509m and has the same age relationships as seen in the type section. Its base is in the Aptian *S. schindewolfii* Zone to 2230m, followed by the Albian *C. cf. vestitum* Zone which occurs between 2210m and 1750m. The formation tops within the Cenomanian *K. williamsii* Zone which ends at 1480m.

In Chebucto G-90 the lowest 18m of the Logan Canyon Formation are in an interval dated as Barremian by foraminifera (undiagnostic by palynology). It is in Aptian sediments to 2670m. The formation tops within the Albian *C. cf. vestitum* Zone at 2026m.

The Logan Canyon is present between 3395m and 2640m in Evangeline H-98, where it begins within the Early Barremian. The Early Barremian is unconformably overlain by the Albian at 3125m within the Logan Canyon, which tops within the Cenomanian interval which extends between 2795m and 1945m.

In Sambro I-29 a short section of Logan Canyon Formation is present between 3361m and 2382m, entirely within the Aptian *S. perlucida* Zone. As the Aptian is unconformably overlain by the Cenomanian in this well, presumably the upper part of the Logan Canyon was eroded or not deposited.

THE DAWSON CANYON FORMATION:

Overlying the Logan Canyon Formation are several hundred feet of shales and/or mudstones called the Dawson Canyon Formation. The type section of the Dawson Canyon is in the Shell Mississauga H-54 well between 4315' and 3425'. According to Barss et al. 1979, the formation begins within the Cenomanian *K. williamsii* (=*C. polypes*) Zone, contains all of the Turonian *S. longifurcatum* Zone, the Coniacian *O. pulcherrimum* Zone, and Santonian *P. truncigerum* Zone. The formation tops at 3425', presumably in the Campanian, just below what is defined as the *O. operculata* Zone (3331-3104') and above the *P. truncigerum* Zone (3600-3507').

In Alma F-67 the Dawson Canyon Formation begins at 1509m within the top of the Cenomanian *K. williamsii* (=*C. polypes*) Zone, contains all of the Turonian *S. longifurcatum* and Coniacian *O. pulcherrimum* Zones and tops at 3425 just above the base of the Santonian *P. truncigerum* Zone.

The Dawson Canyon Formation is very thin in Chebucto G-90 due to an unconformity (at approximately 1935m) which accounts for all of the Turonian and Coniacian. The base of the formation is within the top of the Albian *C. cf. vestitum* Zone at 2026m. It contains all of the Cenomanian *K. williamsii* (=*C. polypes*) Zone and tops just below the top of the Santonian *P. truncigerum* Zone at 1907m.

In Evangeline H-98 the Dawson Canyon Formation is missing due to an unconformity resulting from the loss of or nondeposition of Late Cenomanian through Early Campanian sediments.

The Dawson Canyon Formation is not defined in Sambro I-29.

THE WYANDOT FORMATION:

Perhaps the most distinctive and widely recognized lithologic unit on the Scotian Shelf is the Wyandot Chalk. This formation consists of a chalky carbonate, white to light greenish gray in color and grading both laterally and vertically from pure chalk to marl. The type section was designated by McIver 1972, in the Shell MicMac H-86 well between 2730' and 2440'. According to Jansa and Wade 1975b, the occurrence of chalk or limestone strata interbedded with marls requires an expansion of the original definition of the Wyandot Formation from the uppermost chalk bed described by McIver to a dominately chalky formation with marl and calcareous shale interbeds represented by the interval from 6002' to 4700' in the Mobil Tetco Dauntless D-35 well.

The Shell MicMac H-86 well was not included in Barss et al. 1979, however the original type section was examined by Lentini, 1975 (consultants report). The base of the chalk coincides with the base of the Santonian *P. truncigerum* Zone and has its top near the top of the Campanian *O. operculata* Zone. It is interesting that the expanded definition of the formation, represented by the beds from 6002' to 4700' in Dauntless D-35, does not include any of the Santonian but instead contains both the Campanian *O. operculata* Zone and the Maastrichtian *D. euclaensis* Zone as defined by Barss et al. 1979.

Only twelve meters of Wyandot Formation is defined in Alma F-67 between 1325m and 1313m. The entire interval is within the lower part of the Santonian *P. truncigerum* Zone.

In Chebucto G-90 the Wyandot Formation begins within the lower part of the Campanian *O. operculata* Zone and is truncated by an unconformity at 1768 which accounts for the Maastrichtian.

The Wyandot Formation is indicated between 2014m and 1856m in Evangeline H-98. Based on the palynology, this would place the base of the formation in the Cenomanian with its top within the Campanian. An unconformity accounting for the Turonian, Coniacian and Santonian occurs at about 1935m, in the middle of the Wyandot Formation. This seems highly unlikely. It is reasonable to suggest that the base of the Wyandot rests unconformably on the Dawson Canyon at 2014 and a zone of mixed fossils that occur between 2014m and 1945m accounts for the unconformity being placed too high by palynology.

The Wyandot Formation is not present in Sambro I-29.

THE BANQUEREAU FORMATION:

The post Wyandot, latest Cretaceous sequence and the entire Tertiary system were designated the Banquereau Formation by

McIver 1972. The type section was chosen from the Mobil Sable Island C-67 well between 4459' and 554'. According to Barss et al. 1979, this interval begins in the base of the Maastrichtian between the Campanian *O. operculata* Zone (4515-4468') and the Maastrichtian *D. euclaensis* Zone (4430-4104'). Above the Maastrichtian a complete sequence of Tertiary sediments is recorded within the formation.

In Alma F-67 the base of the Banquereau Formation is at 1313m within the lower part of the Santonian *P. truncigerum* Zone. The palynological evidence suggests a conformable sequence of Late Cretaceous from this point up to the first sample at 840m. However, the micropaleontological evidence suggests that the Maastrichtian is unconformably overlain by the Eocene at 880m.

The Chebucto G-90 well history report does not mention the Banquereau Formation. However, the Campanian Wyandot Formation is unconformably overlain by a relatively complete section of Tertiary (Paleocene into the Miocene) sediments.

In Evangeline H-90 the base of the Banquereau occurs within the Campanian at 1856m. The Campanian is overlain by the Maastrichtian and Paleocene, which is unconformably overlain by the Oligocene and Miocene.

The Banquereau Formation does not occur in Sambro I-29.

Chapter 2

PALEONTOLOGICAL SUMMARY

INTRODUCTION:

The four preceding reports have segregated the palynological analysis from micropaleontological analysis in accordance with the format requested by the GSC. This summary discusses the differences between the two sets of results. Figure 4 graphically illustrates similarities and differences in age determinations in the wells examined. The micropaleontology was not completed for Evangeline H-98.

UNION et al. SAMBRO I-29

Sambro I-29 was analyzed between 1430' and 5980' for micropaleontology and 1430' and 5780' for palynology. In addition, one composite palynological sample was analyzed from the interval 9860-10070'. Palynological and micropaleontological zones were recognized in the well (figures 5 and 6, respectively).

The lower part of the interval analyzed was deposited under marginal marine conditions. This was followed by a period of marine inner neritic sedimentation and then by outer neritic sedimentation in the upper two hundred feet of the interval analyzed.

The sample from 9860'-10070' contained a very sparse Mid to Late Jurassic marine palynoflora. A section from 5780' to 4040' was virtually barren, containing very few palynomorphs which may have been caved. This was followed by a Barremian section, from 3980' to 3485' and by an Aptian section from 3380' to 2360'. An unconformity appears to be present between 2360' and 2300', with Aptian sediments overlain by Cenomanian sediments. Another unconformity, between 2180' and 2120' results in Cenomanian sediments overlain by Coniacian sediments. The top of the Coniacian was identified at 1700' and the interval between 1640' and 1430' could not be dated more closely than Late Cretaceous.

The micropaleontological analysis presents different results. The age of the section up to 5350' is uncertain. Above this level, an uninterrupted sequence of Early and Late Cretaceous age was identified, with sediments of undifferentiated Aptian to Hauterivian age from 5280' to 3640', of Aptian age from

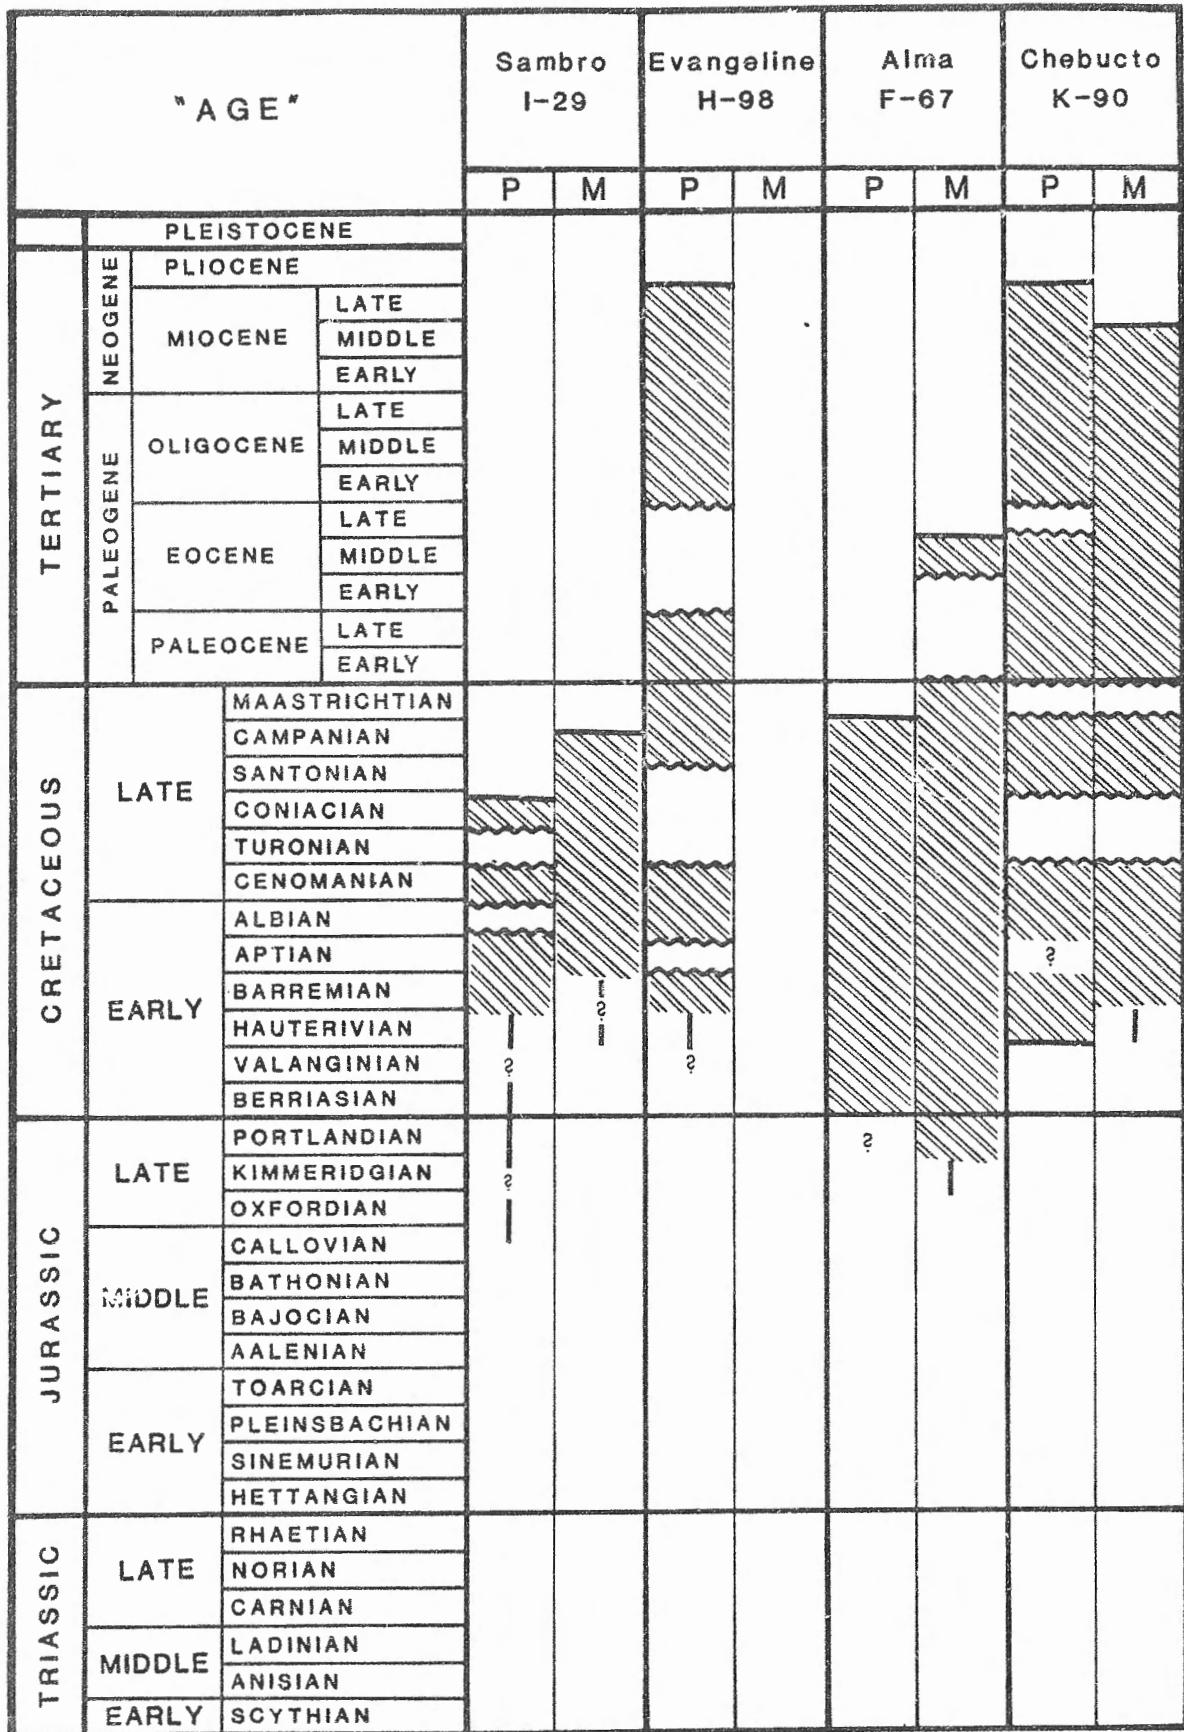

Figure 4 Palynological and Micropaleontological ages of sediments in Scotian Shelf wells.

3580' to 3350', Albian age from 3290' to 2630', Cenomanian from 2570' to 2540', Turonian from 2460' to 2360', Cenomanian or Turonian from 2300' to 2030', Coniacian from 2000' to 1700', Santonian from 1640' to 1520' and Campanian from 1460' to 1430'.

The discrepancies between palynological and micropaleontological results may be due at least in part to the extensive reworking of Lower Cretaceous fossils which was noticed in all the wells in this study and also to the presence of large amounts of Tertiary cavings which masked the picture in the upper part of the section studied.

HUSKY BOW VALLEY et al. EVANGELINE H-98

The Evangeline H-98 well was analyzed palynologically from 995m to 5045m (T.D.). Micropaleontological analysis was not carried out on this well. Figure 7 shows the palynological zonation.

The sediments in this well were deposited entirely under marine conditions. The lower portion of this well was found to be barren up to 4780m. The sediments between 4760m and 3940m could not be dated any more closely than Early Cretaceous undifferentiated due to a paucity of fossils. This was overlain by an Early Barremian section from 3920m to 3145m. An unconformity caused the erosion of most of the Barremian and the Aptian sediments and brought Albian sediments directly above Early Barremian sediments at 3125m. The top of the Albian was recognized at 2815m. The overlying Cenomanian extends from 2795m to 1945m. An unconformity is present between 1945m and 1925m, with the Cenomanian unconformably overlain by the Campanian. The exact level of this unconformity is probably masked by extensive reworking and placed too high by palynological means alone. It should more reasonably be placed at the lithological break at 2014m, as discussed in the Stratigraphy section of this report. The Campanian is represented by 130m of sediments in this well, with its top at 1795m. It is followed by the Maastrichtian, from 1775m to 1580m, and the Paleocene from 1560m to 1520m. The Paleocene is unconformably overlain by the Oligocene, which extends from 1500m to 1315m, and is followed by the Miocene from 1295m to the highest sample analyzed, 995m.

SHELL PCI et al. ALMA F-67

The Alma F-67 well was analyzed from 840m to 4935m (T.D.). Both palynological and micropaleontological analyses were com

Figure 7. Palynological Zonation of Evangeline H-98.

pleted on this well. Figures 8 and 9 show the palynological and micropaleontological zonations for this well.

In the lower portion of the well, from TD up to 4200m, sedimentation took place along an oscillating shoreline, as indicated by alternating littoral and inner neritic environments. Above this level, sedimentation was marine, shifting between inner and outer neritic. A considerable shallowing began at 3250m, with marginal marine sedimentation up to 2880m. An abrupt change of environment, which may indicate an unconformity, occurs between 2880m and 2840m, with outer neritic sediments directly overlying marginal marine sediments. After this brief episode of outer neritic sedimentation, a shallowing took place and sedimentation oscillated between marginal marine and inner neritic up to 1410m. Above this level, a gradual deepening brought variable inner to outer neritic conditions up to the last sample analyzed at 840m.

Palynological analysis reports a barren section from 4935m to 4140m. This is followed by an undiagnostic section up to 3690m. The section between 3670m and 3510m was dated as Valanginian-Berriasian, overlain by the Hauterivian between 3490m and 3270m. The Early-Mid Barremian was represented between 3250m and 2940m. This was followed unconformably by the Aptian, from 2920m to 2230m, the Albian from 2210m to 1750m, the Cenomanian from 1730m to 1480m, the Turonian from 1450m to 1410m, the Coniacian from 1390m to 1350m, the Santonian from 1330m to 960m, the Campanian from 940m to 890m, and Late Cretaceous undifferentiated from 880m upwards.

The micropaleontological analysis revealed the presence of Late Jurassic sediments in the lower portion of the well, up to 4020m, corresponding mostly with the portion of the well which was barren of palynomorphs. There is good agreement between the two disciplines over the Valanginian-Berriasian and the Hauterivian tops. The Barremian age suggested by micropaleontology for the interval 2535m - 2840m does not agree with the palynological age of Aptian for this interval. Late Barremian palynological species were not present in the well, possibly due to environmental causes or an unconformity. There is agreement regarding the top of the Aptian. There is no agreement as to the thickness of the Albian, but it should be noted that the evidence for placing the top of the Albian at 1750m by palynology is very strong, whereas the micropaleontological top at 2230m is based on very few species. There is good agreement for the positions of the Cenomanian, Turonian and Coniacian tops, after which the two disciplines diverge considerably in the results. Micropaleontological evidence indicates Maastrichtian and Eocene sediments, which were not recognized by palynology.

Figure 9. Micropaleontological Zonation
of Alma F-67.

The Chebucto G-90 well was analyzed from 415m to 5234m (T. D.) for micropaleontology and from 440m to 5234m for palynology. Figures 10 and 11 show the palynological and micropaleontological correlations for this well.

The environment of deposition was essentially non marine up to 3320m, except for an interval at 4300m to 4500m in which a slight marine influence was intermittently indicated. The marine influence was again obvious in an interval between 2500m and 3200m. Above this interval, and all the way to 2000m, the environment of deposition was considered non marine by micropaleontology, however, the interval does contain dinoflagellates. From 2000m to about 600m the depositional environment is marine, outer neritic between 1800m and 1200m. From 600m to 415m the environment is shallow inner neritic to marginal marine.

The lowermost portion of this well, below 5200m contains a single specimen of *Occisucysta* sp. A, Bujak & Williams '78 which suggests a tentative Hauterivian age. According to palynology this is overlain by a very thick Barremian sequence up to 3430m, however, micropaleontology locates the top of the Barremian at 3320m. This may be more reliable than palynology, as above the palynologic top is an interval, up to 2670m, which does not contain sufficient palynomorphs to be dated. This is followed by a palynologic Albian sequence which is 645m thick, up to 2005m. The lower part of the Albian interval corresponds to a non marine Aptian interval according to micropaleontology. It is possible that environmental causes prevented Aptian fossils from being deposited, and that Albian fossils caved into barren sediments, thus accounting for the absence of the palynological Aptian record. Micropaleontology does recognize a thick Aptian, from 2275m to 3300m; and an Albian section up to 2035m. Thus there is quite good agreement between the two discipline lines as to the top of the Albian. The Albian is conformably overlain by a thin (40m) Cenomanian interval, from 1925m to 1945m based on palynology. The micropaleontological interpretation indicates this to be 100m thick, up to 1915m, according to both disciplines, an unconformity separates the Cenomanian from the Santonian, resulting in the absence of Turonian and Coniacian record. The location of the unconformity is at approximately 1935m by palynology and 1910m by micropaleontology. The top of the Campanian is given at 1765m by micropaleontology and at 1795m by palynology. Both disciplines identify an unconformity, with the Paleocene resting on the Campanian.

The Tertiary sequence is considered to be continuous by both disciplines. However, the stage boundaries by the two disciplines do not always agree in detail. The top of the Paleocene is at 1650m by both disciplines. The subdivisions of the Eocene do not agree. Palynology usually recognizes an early Oligocene

interval which is dated as late Eocene by micropaleontology. This difference is probably semantic, in view of this fact, the two disciplines are in fairly good agreement as to the top of the Eocene. A thin Miocene section was recognized by palynology but not by micropaleontology.

LOCATION OF FORAMINIFERA AND OSTRACODE SPECIES

Chebucto G-90

Turborotalia opima opima (440-50, sq. 6).
Globigerina cf. praebulloides (440-50, sq. 18)
Globigerina cf. bulloides (470-80, sq. 8)
Globigerina cf. trilobus (500-10, sq. 20)
Globigerina cf. senelis (540-50, sq. 18)
Globigerina ouachitaensis (570-80, sq. 5)
Orbulina universa (750-60, sq. 21)
Globigerina officinalis (840-50, sq. 19)
Globigerina cf. tripartita (840-50, sq. 32)
Marginulina cf. glabra (415-25, sq. 5)
Nonionella auris (480-90, sq. 31)
Textularia cf. badensis (470-80, sq. 22)
Cibicides floridana (540-50, sq. 7)
Planulina depressa (570-80, sq. 6)
Uvigerina cf. danvillensis (630-40, sq. 18)
Marginulina subperba (630-40, sq. 31)
Pullenia bulloides (630-40, sq. 19)
Hoeglundina cf. eocenica (630-40, sq. 30)
Plectofrondiculina vaughan (720-30, sq. 5)
Marginulinopsis tuberculata (720-30, sq. 7)
Melonis planatus (720-30, sq. 20)
Nodosaria stainforthi (720-30, sq. 19)
Sphaeroidina cf. bulloides (720-30, sq. 18)
Heterolepa peppeni (720-30, sq. 17)
Bulimina inflata (720-30, sq. 31)
Tritaxia alazanensis (750-60, sq. 8)
Uvigerina cf. yazooensis (750-60, sq. 19)
Gyroidinoides cf. soldani (750-60, sq. 9)
Oridorsalis umbonatus (750-60, sq. 22)
Spiroplectammina mississippiensis (780-90, sq. 7)
Bolvina cf. gardnerai (780-90, sq. 31)
Globocassidulina subglobosa (780-90, sq. 8)
Stilostomella curvatura (780-90, sq. 20)
Melonis pomiliodes (810-20, sq. 21)
Globorotalia cennetralis (960-70, sq. 8)
Globigerina venezuelana (1380-90, sq. 20)
Globigerina eocaena (1380-90, sq. 22)
Siphonina danvillensis (960-70, sq. 7)
Hoeflündina eocenica (960-70, sq. 9)
Ceratobulimia af. eximia (960-70, sq. 33)
Nodosaria lamellata (960-70, sq. 32)
Stilostomella cookei (960-70, sq. 22)

Uvigerina cf. glabrans (960-70, sq. 10)
Heterolepa pseudoungerinaus (960-70, sq. 46)
Marginulinopsis texensis (960-70, sq. 20)
Planulina cooperensis (990-1000, sq. 7)
Guttulina elegans (990-1000, sq. 8)
Guttulina spicaeformis (990-1000, sq. 20)
Gyroidinoides cf. soldanii (990-1000, sq. 32)
Massilina decorata (1050-60, sq. 21)
Globocassidulina subglobosa (1050-60, sq. 9)
Marginulina hantkeni (1050-60, sq. 20)
Heterolepa pippeni (1080-90, sq. 21)
Cibicides cf. lobatus (1080-90, sq. 9)
Gyroidinoides planata (1110-20, sq. 9)
Cassidulinoidea sp. #CA (1140-50, sq. 6)
Bulimina cooperensis (1170-80, sq. 7)
Uvigerina cocoaensis (1200-10, sq. 6)
Uvigerina cocoaensis (1230-40, sq. 7)

Marssonella cf. *oxycona* (3510-20, sq. 33)
Lenticulina saxonica saxonica (3540-50, sq. 20),
Lenticulina cf. *saxonica bifurcilla* 3540-50, sq. 21),
Conorotalites cf. *bartensteini* (3540-50, sq. 22),
Eoepnidella sp. #CA 3540-50, sq. 34),
Tristix insigne (3570-80, sq. 19),
Caucasella hoterivica (3570-80, sq. 20),
Lingulina nodosaria (3630-40, sq. 19),
Pseudotextulariella sp. #CA (3630-40, sq. 31),
Patellina sp. #CA (3660-70, sq. 21),
Conorboides hofkeri (3660-70, sq. 20),
Vaginulinopsis recticulosa (3690-3700, sq. 20),
Marssonella hauteriviana (3780-90, sq. 19),
Ammodiscus cretaceous (3930-40, sq. 17)
Epistomina uhligi (4050-60, sq. 9),
Epistomina stellicostata (4050-60, sq. 21),

Marginotruncana marginata (1430-60, sq. 31)
Gaudryina austinana (1430-60, sq. 9)
Neoflabellina deltoidea (1430-60, sq. 8)
Kyphopyxa christneri (1430-60, sq. 19)
Vaginulina wadei (1430-60, sq. 7)
Nodosaria affinis (1430-60, sq. 6)
Lenticulina munsteri (1430-60, sq. 30)
Epistomina stelligera alveolata (1430-60, sq. 42)
Hoeglundina supracretacea (1430-60, sq. 43)
Arenobulimina subsphaerica (1430-60, sq. 44)
Pseudolamarckina (?) sp. #CA (1430-60, sq. 18)
Marginulina silicula (1430-60, sq. 32)
Haplocytheridea globosa (1430-60, sq. 20)
Cythereis ornatissima (1430-60, sq. 21)
Brachycythere cf. ovata (1430-60, sq. 33)
Archaeoglobigerina blowi (1610-40, sq. 6)
Dorothia conula (1520-50, sq. 7)
Vaginulina texana (1520-50, sq. 8)
Gyroidinoides globosa (1520-50, sq. 20)
Gavelinella stephensoni (1520-50, sq. 19)
Veenia sp. #CA (1520-50, sq. 9)
Brachycythere sphenoides (1610-40, sq. 7)
Whiteinella paradubia (1790-1820, sq. 9)
Heterohelix cf. *moremani* (1970-2000, sq. 21)
Epistomina stelligera s.s. (1700-30, sq. 8)
Vaginulina cretacea (1700-30, sq. 20)
Praebulimina cf. *reussi* (1790-1820, sq. 8)
Gyroidinoides depressa (1970-2000, sq. 8)
Gyroidinoides cf. *umbilicatus* (1970-2000, sq. 20)
Globorotalites multiseptus (1970-2000, sq. 32)
Gavelinella ammonoides (1970-2000, sq. 33)
Haplocytheridea cf. *plummeri* (1700-30, sq. 7)
Neocythere annulospinata (1970-2000, sq. 18)
Dicarinella algeriana (2450-80, sq. 8)
Hedbergella delrioensis (2450-80, sq. 20)
Ammobaculites comprimatus (2450-80, sq. 19)
Palmula cf. *cushmani* (2360-90, sq. 31)
Coscinophragma (?) sp. #CA (2360-90, sq. 19)
Cythereis af. *eaglefordensis* (2540-70, sq. 17)
Whiteinella baltica (3080-3110, sq. 19)
Dorothia af. *filiformis* (2630-60, sq. 31)
Epistomina cretosa (2630-60, sq. 20)
Ammobaculites reophacoides (2630-60, sq. 19)
Lenticulina cf. *gaultina* (2630-60, sq. 32)
Protocythere alexanderi (2720-50, sq. 20)
Eocytheropteron (?) sp. #CA (2720-50, sq. 19)
Alatocythere sp. #CA (2720-50, sq. 32)
Neocythere annulospinata (2810-40, sq. 19)
Rehacythereis af. *dentonensis* (2810-40, sq. 19)
Schuleridea jonesiana (3080-3110, sq. 18)
Protocythere speetonensis (3170-3200, sq. 19)
Orthonatocythere sp. #CA (3170-3200, sq. 18)
Epistomina sp. #CA (3350-80, sq. 31)
Lenticulina nodosa (3540-80, sq. 20)
Ceratolamarckina (?) sp. #CA (3540-80, sq. 20)
Gaudryinella tealbyensis (3540-80, sq. 19)
Trocholina cf. *infragranulata* (5250-80, sq. 4)

INTEGRATED BIOSTRATIGRAPHY

**OF
CHEBUCKTO G-90**

440-550m	Miocene.
570-970m	Oligocene.
1140-1450m	Late Eocene.
1470-1570m	Middle Eocene.
1590-1630m	Early Eocene.
1650-1720m	Late Paleocene.
1740-1750m	Early Paleocene.

-Unconformity-

1765-1865m	Campanian.
1885-1915m	Santonian.

-Unconformity-

1915-1985m	Cenomanian.
2005-2255m	Albian.
2275-3300m	Aptian.
3320-5180m	Barremian.
5200-TD	Hauterivian.
