INTRODUCTION

A regional till geochemical survey was initiated in Northern and Central New Brunswick, in the summer of 1985, as part of a Quaternary geology and till geochemistry project funded through the Canada-New Brunswick Mineral Development Agreement (1984-89). The main objective of this project was to study the variability of the geochemistry of till overlying rocks of the Miramichi Zone and its vicinity. Specific objectives of this project were described in Lamothe (1988).

The geochemical analyses are released as Open Files. A series of five reports present the geochemical results obtained through (1) a deep overburden drilling program in the St. John River Valley and along the Chaleur Bay coastal area (Lamothe, 1990a), (2) a detailed trenching project carried out in the vicinity of tin-bearing granites of Central New Brunswick (Lamothe, 1990b), and (3) regional geochemical surveys carried out over the Northern, Central, and Southern portions of the Miramichi Zone. The subdivision of the Miramichi Zone into three sub-zones was adopted for sake of readability of the geochemical data, since more than 3500 till samples were collected in the course of the regional surveys. It also appears that these sub-zones reflect specific geological and lithogeochemical contexts.

This report presents the results of the geochemical analyses available for the Northern part of the Miramichi Zone. Partial results were published earlier (Lamothe, 1988). This report releases the raw geochemical data without interpretation. It includes tables of geochemical results as well as a series of single-element geochemical maps at the 1: 500 000 scale. There are many factors that control the abundance of the elements of economic interest in this area (e.g. bedrock mineralization, near-surface geochemical processes, glacial dispersal etc). These variables will be assessed and discussed in a later publication.

A) LOCATION AND BEDROCK GEOLOGY OF THE AREA

Till sampling was mostly carried over the Charlo (21O/16), Pointe Verte (21P/13), Bathurst (21P/12), Nepisiguit Lakes (21O/7), California Lake (21O/8), and Nepisiguit Falls (21P/5) map sheets (Plates 1 to 8). Limited sampling was also implemented during the summer of 1985 over adjoining Tetagouche Lakes (21O/9) and Upsalquitch Forks (21O/10) map sheets. The area under study is limited by latitudes $47^{\circ}15'$ and $48^{\circ}05'$, and longitudes $65^{\circ}30'$ and $67^{\circ}00'$.

The bedrock geology of the area is shown on Figure 1. There, three of the preCarboniferous tectonostratigraphic zones defined by Ruitenberg *et al.* (1977) are bounded by major fault systems. These three zones are:

- (1) the Miramichi zone, consisting of Ordovician and perhaps older metamorphosed and highly deformed volcanic, sedimentary and intrusive rocks (Tetagouche Group);
- (2) the Elmtree Zone, an uplifted block of deformed gabbro, amphibolite, peridotite, basalt, greywacke, and slate of the Ordovician Elmtree and Fournier Groups;
- (3) the Tobique-Chaleur Zone, an assemblage of Ordovician, Silurian, and Devonian sedimentary, volcanic and intrusive rocks.

Numerous Devonian granitic stocks are found as isolated intrusive bodies throughout the region. These terrains are overlain by a post-tectonic Carboniferous (mainly Pennsylvanian) cover consisting of undisturbed clastic sedimentary rocks.

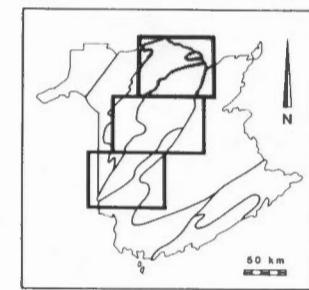

The major mineral occurrences of Northern New Brunswick are plotted on Figure 1 as undifferentiated diamonds. For a list of mineral occurrences by type of occurrence, the reader is referred to Davies (1977; Map NR-3). These include the major sulphide bodies in the Bathurst Mining Camp (Skinner, 1974). A series of new occurrences have been discovered since the publication of this map. Most of these are gold showings which were found as the result of prospecting and, in a few cases, follow-up of earlier geochemical surveys (Boyle *et al.*, 1965; Pronk and Burton, 1988). In the course of this project, Gagnon (1987) described the geochemistry of samples of till collected over the Discovery Zone at Alcida. Discussions of some of the factors that control the regional till geochemistry have been published by Pronk and Lamothe (1988), Pronk (1987), and Lamothe (1988).

B) QUATERNARY GEOLOGY

A summary of the ice flow patterns and geomorphology of Northern New Brunswick has been presented by Rampton *et al.* (1984) and updated in Pronk and Lamothe (1988). Only a brief review is presented here.

Simplified from Davies (1977)

The area shows evidence for a series of ice flows events. The sequence of ice flows can be assessed from the study of small-scale erosional forms such as striae and crag-and-tail features as well as larger landforms such as fluted surfaces and drumlinoids. The oldest ice flow, documented in a few localities, was southeastward. This was followed by an eastward and a northeastward ice flow, these being probably the ice flows that controlled most of the glacial transport that can be deduced from the provenance studies available so far (Gauthier, 1982, 1983; Pronk and Lamothe, 1988; Gagnon, 1987; Lamothe, 1988). No significant glacial transport is associated with late glacial regional ice flows, which were southward in the Pointe Verte area, and northward over the Northern Miramichi Highlands (Pronk, 1987).

Even though sub-till nonglacial sediments were recovered in boreholes drilled in the vicinity of Charlo (Lamothe, 1990a), it seems that only one till sheet is present. In the area, till is generally thin and locally derived. The bulk of the glacial debris was transported in an eastward to east-northeastward direction, for distances rarely exceeding 1 km.

A late glacial marine transgression along the Chaleur Bay coastal area left a sequence of pitted deltas, beach and offshore sediments (Brobowksy *et al.*, 1987). This is the reason for the low sampling density in the coastal areas.

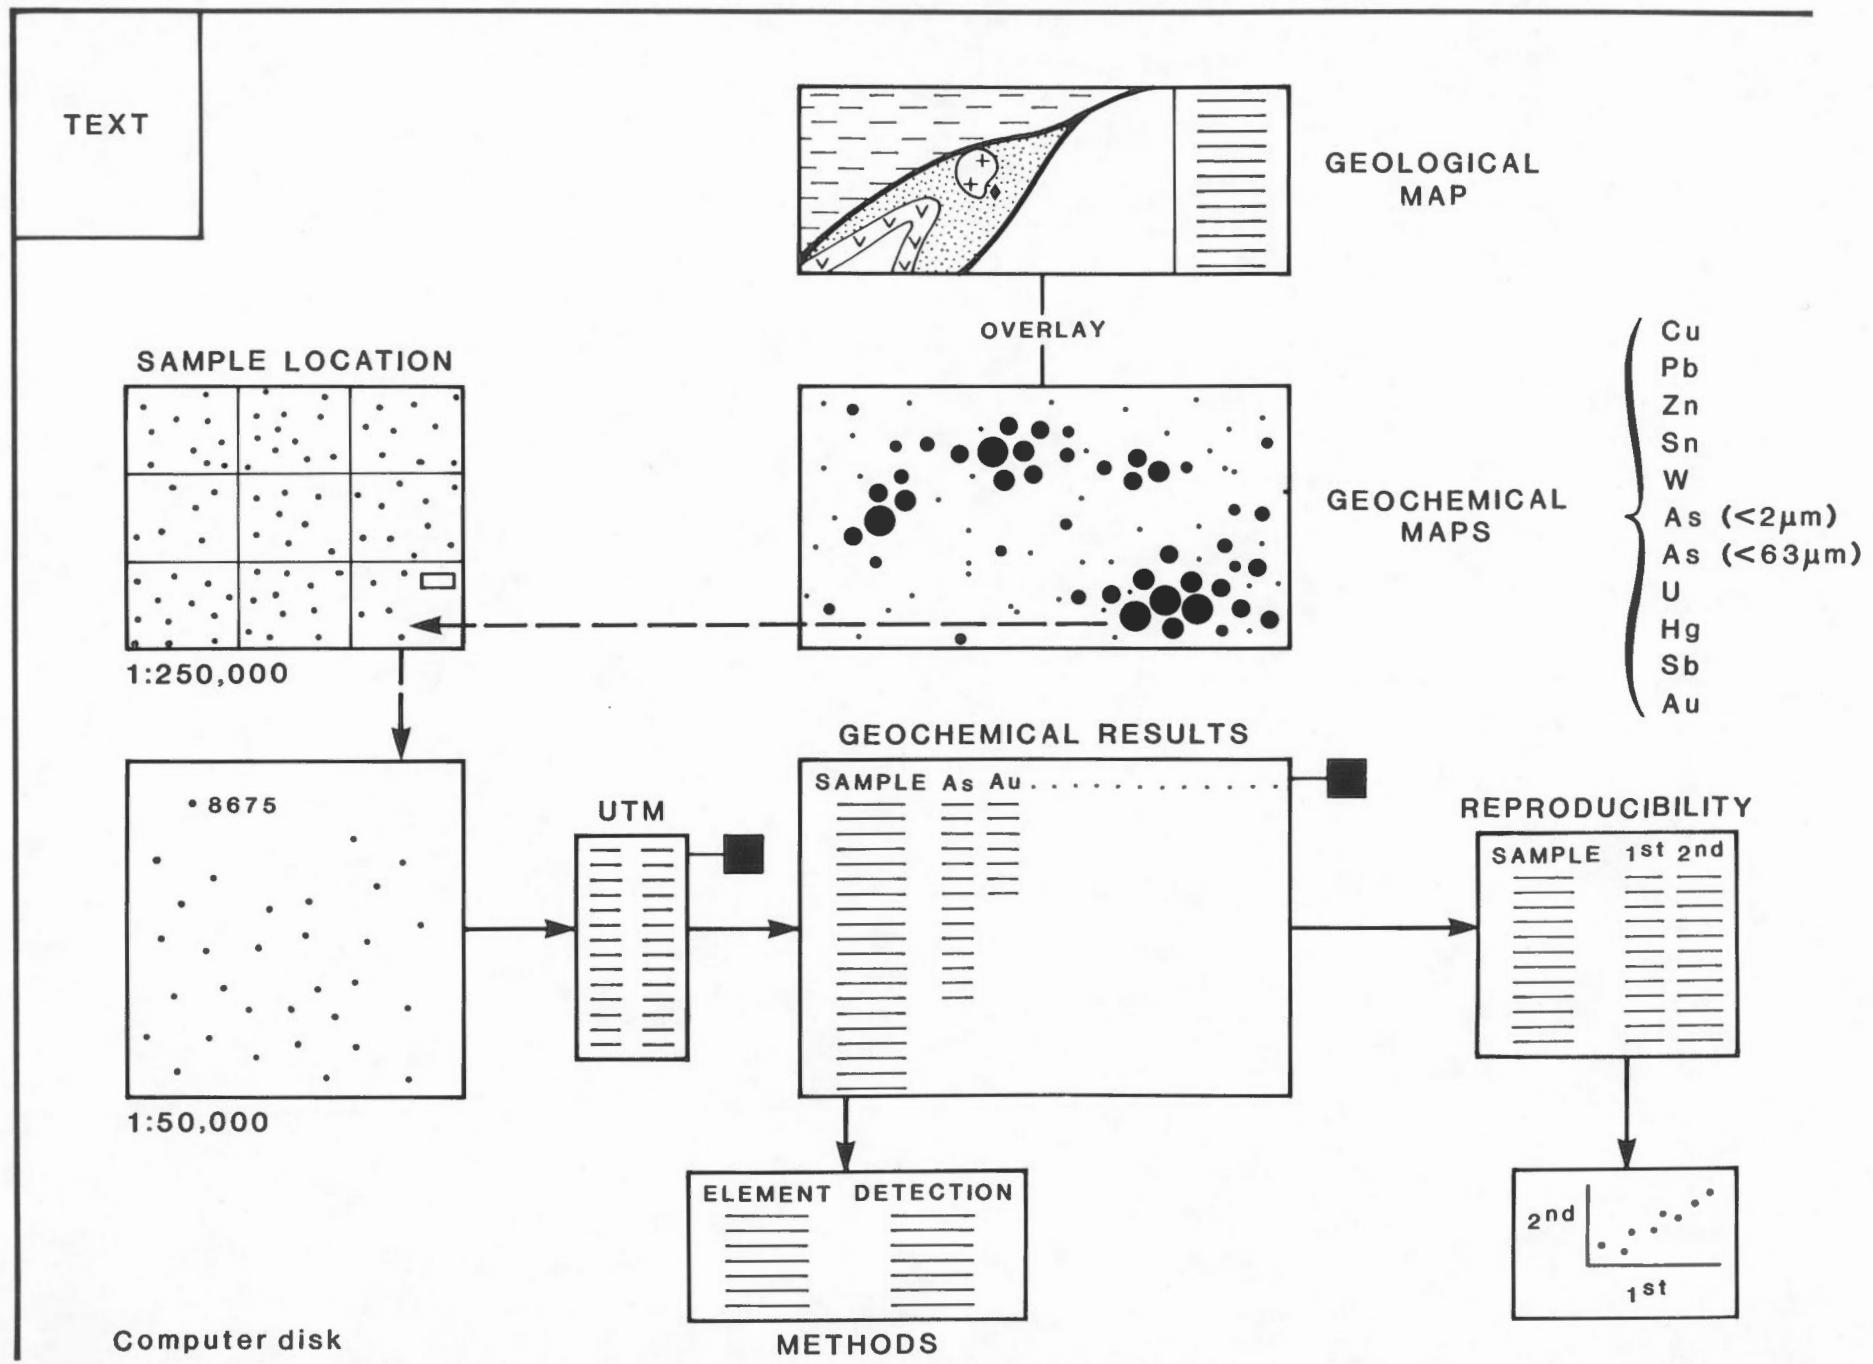

C) GEOCHEMICAL METHODS AND RESULTS

Sampling was initially carried out at roadside and natural exposures. In areas of low accessibility, traverses were made to increase the sample density to approximately 1 site per 6 km^2 . The location of the samples can be found on Table I and Plates 1 to 8. The results of detailed geochemical studies have been published earlier (Lamothe, 1988, Lamothe, 1990a).

The organization of this report is illustrated on Figure 2. Anomalous samples can be quickly located from any 1:500 000 geochemical map and/or the corresponding geochemical analysis (Tables III and IV) using the 1:250 000 location map (Plate 1) from which the 1:50 000 map sheet can be identified. Each sample is plotted on the individual 1:50 000 map sheets (Plates 2 to 11) and located with respect to the UTM grid in Table I.

Figure 2

THE OPEN FILE SYSTEM

Samples were initially sent to the Sedimentology and Mineral Tracing Laboratory of the Terrain Sciences Division (Geological Survey of Canada), in Ottawa. From there, the samples were shipped to Bondar Clegg and Co. Ltd until 1986, and to Chemex Labs Ltd for samples collected thereafter. The change in analytical facilities was the result of contracting-out via competitive bidding. This might have caused problems in comparisons of pre- and post-1986 data. After pulp preparation, the samples were sent to the GSC for preparation of duplicates. The pulp samples were then shipped back to the analytical laboratories for geochemical analysis.

Two grain-size fractions were analysed for each till sample. The clay-sized ($<2\text{ }\mu\text{m}$) fraction was analysed for Ag, As, Co, Cr, Cu, F, Fe, Hg, Mn, Mo, Na, Ni, Pb, Sn, U, W, and Zn (1368 analyses; 974 sites). It was shown by Shilts (1984) that most of the base-metals will be concentrated in the fine-grained fraction of the till. The clay plus silt ($<63\mu\text{m}$) fraction was analysed for As, Au, Co, Cr, Fe, Hg, Mo, Ni, Sb, Th, U, and W (1105 analyses; 963 sites). This granulometric fraction is thought to be more reliable for gold and antimony (DiLabio, 1982; Gleeson *et al.*, 1984). The geochemical methods and detection limits for each element will be found on Table II. The geochemical results are presented on Tables III and IV. Because many samples have been analysed more than once, reproducibility of the geochemical analyses and interlaboratory comparisons could be assessed (Tables V to VIII).

Single-element geochemical maps (scale 1:500 000) are presented on Plates 9 to 19. The averaged geochemical results for each sampling site were used for processing maps and statistics. Half of the detection limit was used as the value for samples in which a specific element was not detected. The regional single-element geochemical abundance is superimposed on the bedrock geology, simplified from Davies (1977). On the maps, the abundance of any element is proportional to the size of a logarithmically-scaled dot. The plotting of the dots is such that a low abundance sample is not obscured by a nearby high abundance sample. Data processing was insured by Terrain Sciences Division through a contract to Northwood Geoscience Inc. (Ottawa), and its own computer facilities. A normal probability plot, a simple frequency histogram, and a diagram illustrating the reproducibility of the data are included on each map.

ACKNOWLEDGEMENTS

This study was funded through the Canada-New Brunswick Mineral Development Agreement (1984-89). The Department of Supply and Services (Government of Canada) awarded a contract to the Université du Québec à Montréal which allowed the use of its facilities to the author in order to achieve this report. Thanks are due to W.W. Shilts (Terrain Sciences Division) for his advice and support throughout the operation. During field work, collaboration from many geologists working in the area was of great help. Amongst others, the author would like to thank D. Hoy of Lacana Mining Co. and D. Burton then under contract with NBDNR. Till sampling was mostly carried out by field assistants. They are kindly acknowledged. The author would like to thank also M. Laithier (Université du Québec à Montréal) for drafting, and P.H. Wyatt (Northwood Geoscience Inc.), E. Boisvert (Université du Québec à Montréal), and S.J. Courtney (Terrain Sciences Division) for data processing.

NOTES TO TABLES III TO VIII

- 1) "Blank" = not analysed
- 2) "Obs" = laboratory e.g. 1,2,3 ... Bondar Clegg and Co. Ltd
10,11,12... Chemex Labs Ltd
- 3) Half the value of the detection limit is indicated when the element is not detected, e.g. Au = 1.0 ppb means Au <2.0 ppb
- 4) Sample number= YY LFA XXXX NN
YY=Year of sampling , LFA=Project leader's code
XXXX=Code number of sample site , NN = Sample number
- 5) NN: 01= 0.80 m, from the surface,
NN: 02= 1.60 m, from the surface,
NN: 03= 2.40 m, from the surface, etc.
