INTRODUCTION

A regional till geochemical survey was initiated in Northern and Central New Brunswick, in the summer of 1985, as part of a Quaternary geology and till geochemistry project funded through the Canada-New Brunswick Mineral Development Agreement (1984-89). The main objective of this project was to study the variability of the geochemistry of till overlying rocks of the Miramichi Zone and its vicinity. Specific objectives of this project were described in Lamothe (1988a).

The geochemical analyses are released as Open Files. A series of five reports present the geochemical results obtained through (1) a deep overburden drilling program in the St. John River Valley and along the Chaleur Bay coastal area (Lamothe, 1990a), (2) a detailed trenching project carried out in the vicinity of tin-bearing granites of Central New Brunswick (Lamothe, 1990b), and (3) regional geochemical surveys carried out over the Northern, Central, and Southern portions of the Miramichi Zone. The subdivision of the Miramichi Zone into three sub-zones was adopted for sake of readability of the geochemical data, since more than 3500 till samples were collected over the whole zone. It also appears that these sub-zones reflect specific geological and lithogeochemical contexts.

This report presents the results of the geochemical analyses available for the Central part of the Miramichi Zone. Partial results were published earlier (Lamothe, 1986, 1989). This open file releases the raw geochemical data without interpretation. It includes tables of geochemical results as well as a series of single-element geochemical maps at the 1: 500 000 scale. There are many factors that control the abundance of the geochemical elements of economic interest in this area (e.g. bedrock mineralization, near-surface geochemical processes, glacial dispersal etc). These variables will be assessed and discussed in a later publication.

A) LOCATION AND BEDROCK GEOLOGY OF THE AREA

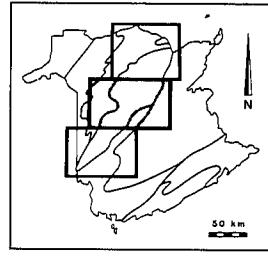

Till sampling was mostly carried over the following map areas (Plates 1 to 11): Riley Brook (21O/3), Serpentine Lake (21O/2), Big Bald Mountain (21O/1), Sevogle (21P/4), McKendrick Lake (21J/16), Tuadook Lake (21J/15, Plaster Rock (21J/14), Juniper (21J/11), Hayesville (21J/10), and Doaktown (21J/9) . The area under study is limited by latitudes 47°15' and 46°30', and longitudes 65°30' and 67°30'.

The bedrock geology of the area (Fig. 1) has been compiled by Fyffe (1982) and Davies (1977). The sampling program was designed to sample till overlying rocks of the Miramichi Zone, one of the tectonostratigraphic zones defined by Ruitenberg *et al.* (1977). In this area, the metasedimentary and metavolcanic rocks of the Tetagouche Group overly a Cambrian (and perhaps older) migmatite complex. Syntectonic foliated Ordovician granite and schistose gabbro are found in contact with the Tetagouche Group. This sequence is intruded by numerous Devonian to Lower Mississippian granitic stocks. Silurian greywackes and slates of the Magaguadavic Zone are found in faulted contact with the rocks of the Miramichi Zone along its southeastern edge. Clastic, volcanic and gabbroic rocks of the Tobique-Chaleur Zone are in contact with the western edge of the Miramichi Zone, by means of a series of faults (e.g. the Catamaran Fault). Relatively undisturbed Mississippian and Pennsylvanian sedimentary rocks unconformably overly the deformed terrains in the western and southeastern part of the area.

The main mineral occurrences are listed on Maps NR-3 and 4 of the New Brunswick Department of Natural Resources, by type of occurrence. Some of those are tin and tungsten mineralizations associated with the Devonian intrusions (Ruitenberg and Fyffe, 1985). They have been recently documented by Fyffe and MacLennan (1988). The only occurrence that has been mined was the Burnt Hill tungsten deposit which ceased production in 1956 (Poole, 1963). At the moment, no major gold mineralization is known to occur in the area.

B) QUATERNARY GEOLOGY

The Quaternary geology of the area has been mapped by Rampton and Paradis (1981) and Rampton *et al.* (1984). Glacial transport was controlled by the Tuadook-Renous ice flow pattern, which can be described as eastward to southeastward in the western part of the area and eastward to northeastward in the eastern part. The regional till sheet overlies nonglacial sediments containing carbonized wood fragments, dated at >35 ka (GSC-4199), at the Half Moon gravel pit, located a few kilometres southeast of Juniper (Lamothe, 1988b). A major belt of desintegration moraine is found close to the Dungarvon River and in the Tuadook Lake area, and it is believed to define a halt during the retreat of the last ice sheet that covered the area. Those deposits are included in a more extended belt known as the Millville/Dungarvon Moraine dated at 12.7 ka (Rampton and Paradis, 1981). However, organic remains dated at 11.5 ka (GSC-4277) have been recovered from the base of the regional till sheet, in the Todd Mountain area (Lamothe *et al.*, 1987; Lamothe, 1990b). This site is located outside of the Millville/Dungarvon glacial limit. In the area, the thickness of the till sheet is generally between 1 and 2 metres, except in the vicinity of the morainic belt where thicknesses in excess of 3 metres are common.. Details about the stratigraphy, the sedimentology, and the geochemistry of the regional till sheet have been presented by Plouffe (1986) and Sacré (1989).

C) GEOCHEMICAL METHODS AND RESULTS

Sampling was initially carried out at roadside and natural exposures. In areas of low accessibility, traverses were made to increase the sample density to approximately 1 sample per 6 km². The location of the samples can be found on Table I and Plates 1 to 11.

The organization of this report is illustrated on Figure 2. Anomalous samples can be quickly located from any 1:500 000 geochemical map and/or the corresponding geochemical analysis (Tables III and IV) using the 1:250 000 location map (Plate 1) from which the 1:50 000 map sheet can be identified. Each sample is plotted on the individual 1:50 000 map sheets (Plates 2 to 11) and located with respect to the UTM grid in Table I.

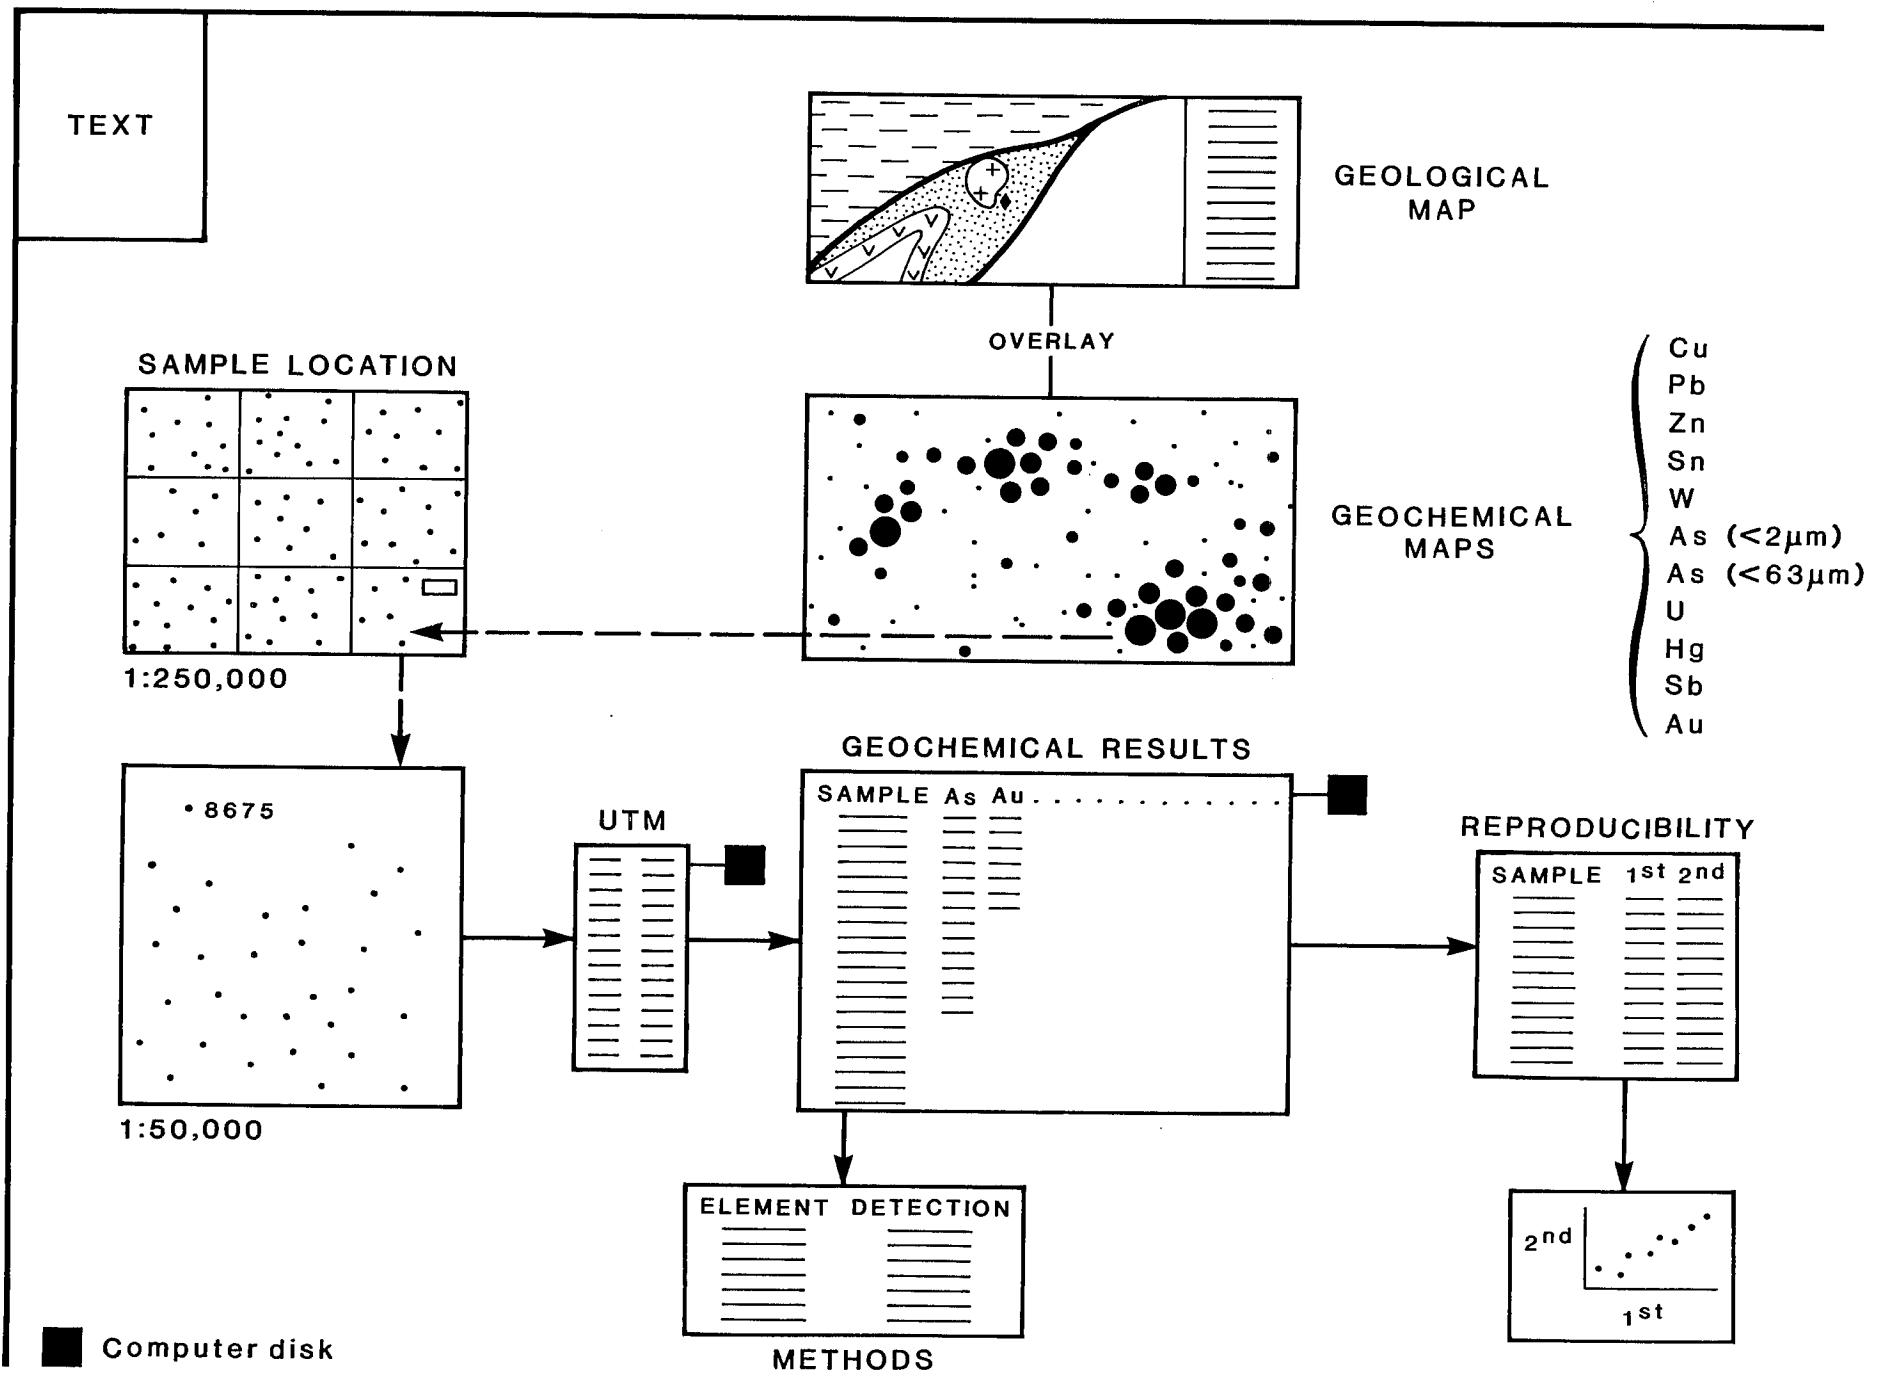

Samples were initially sent to the Sedimentology and Mineral Tracing Laboratory of the Terrain Sciences Division (Geological Survey of Canada), in Ottawa. From there, the samples were shipped to Bondar Clegg and Co. Ltd until 1986, and to Chemex Labs Ltd for samples collected thereafter. The change in analytical facilities was the result of contracting-out via competitive bidding. This might have caused problems in comparisons of pre- and post-1986 data. After pulp preparation, the samples were sent to the GSC for preparation of duplicates. The pulp samples were then shipped back to the analytical laboratories for geochemical analysis.

Two grain-size fractions were analysed for each till sample. The clay-sized (<2 µm) fraction was analysed for Ag, As, Co, Cr, Cu, F, Fe, Hg, Mn, Mo, Na, Ni, Pb, Sn, U, W, and Zn (1731 analyses; 1490 sites). It was shown by Shilts (1984) that most of the base metals will be concentrated in the fine-grained fraction of the till. The clay plus silt (<63 µm) fraction was analysed for As, Au, Co, Cr, Fe, Hg, Mo, Ni, Sb, Th, U, and W (1782 analyses; 1484 sites). This granulometric fraction is thought to be more reliable for gold and antimony (DiLabio, 1982; Gleeson *et al.*, 1984). The geochemical methods and detection limits for each element will be found in Table II. The geochemical results are presented in Tables III and IV. Because many samples have been analysed more than once, reproducibility of the geochemical analyses and inter-laboratory comparisons could be assessed (Tables V to VIII).

Single-element geochemical maps (scale 1:500 000) are presented on Plates 12 to 22. The averaged geochemical results for each sampling site were used for processing maps and statistics. Half of the detection limit was used as the value for samples in which a specific element was not detected.

Figure 2

THE OPEN FILE SYSTEM

The regional single-element geochemical abundance is superimposed on the bedrock geology, simplified from Fyffe (1982) and Davies (1977). On the maps, the abundance of any element is proportional to the size of a logarithmically-scaled dot. The plotting of the dots is such that a low abundance sample is not obscured by a nearby high abundance sample. Data processing was insured by Terrain Sciences Division through a contract with Northwood Geoscience Inc. (Ottawa), and its own computer facilities. A normal probability plot, a simple frequency histogram, and a diagram illustrating the reproducibility of the data are included on each map.

ACKNOWLEDGMENTS

This study was funded through the Canada-New Brunswick Mineral Development Agreement (1984-89). The Department of Supply and Services (Government of Canada) awarded a contract to the Université du Québec à Montréal which allowed the use of its facilities to the author in order to achieve this report. Thanks are due to Dr W.W. Shilts (Terrain Sciences Division) for his advice and support throughout the operation. The author would like to thank W.W. Gardiner, then of Kidd Creek Mines Ltd, for collaboration during the 1985-86 field seasons. Till sampling was mostly carried out by field assistants. They are kindly acknowledged. The author would like to thank also M. Laithier (Université du Québec à Montréal) for drafting, and P.H. Wyatt (Northwood Geoscience Inc.), E. Boisvert (Université du Québec à Montréal), and S.J. Courtney (Terrain Sciences Division) for data processing.

NOTES TO TABLES III TO VIII

- 1) "Blank" = not analysed
- 2) "Obs" = laboratory e.g. 1,2,3 ... Bondar Clegg and Co. Ltd
10,11,12... Chemex Labs Ltd
- 3) Half the value of the detection limit is indicated when the element is not detected, e.g. Au = 1.0 ppb means Au <2.0 ppb
- 4) Sample number= YY LFA XXXX NN
YY=Year of sampling , LFA=Project leader's code
XXXX=Code number of sample site , NN = Sample number
