**INTRODUCTION**

This open file report contains unedited Rock-Eval/TOC data from 14 wells in southwest Alberta. The measured parameters are as follows: S1, hydrocarbons volatile at 300°C reported as mg hydrocarbon/g rock; S2, hydrocarbons volatilized and generated during ramped (25°C/min) pyrolysis between 300°C and 600°C reported as mg HC/g rock; S3, organic carbon dioxide released at 300°C and during ramped heating up to 390°C reported as mg CO<sub>2</sub>/g rock; Tmax, the temperature in °C at the top of the S2 peak; and TOC, total organic carbon as percent by weight of the rock algorithmically determined from the carbon contained in the S1+S2 as well as the oxidation peak, S4. In addition, a number of derived parameters have been reported as follows: PI, Production Index = S1/(S1+S2); HI, Hydrogen Index = 100\*S2/TOC as mg HC/g TOC; OI, Oxygen Index = 100\*S3/TOC as mg CO<sub>2</sub>/g TOC; and S1+S2, or total hydrocarbon capacity as mg HC/g rock. The results are reported as a function of depth in each well in either feet or metres depending on the units in which the well was drilled and the samples originally labelled. The depth units are noted as either F or M in the first line or two of the data set. Because the results are unedited, caution must be used in interpreting any of these results especially if they are not used within the context of results for adjacent samples.

**INDEX OF WELLS**

## **RESULTS AND DISCUSSION**

### **Petroleum Source Potential**

Petroleum source potential is defined by three geochemical parameters: 1) the level of thermal maturity, 2) the quantity of organic, and 3) the type of organic matter. These parameters define both the quantity and type of product (heavy oil, oil, condensate or gas) that will be generated in a source rock in response to geothermal stress. In combination with kinetic parameters and a burial history (geology), these data can be used as input parameters for a mathematical model of hydrocarbon generation through time as well as providing ground truth or target values for the model for the present time as a function of present depth.

### **Thermal Maturity**

The sections represented in the wells in this study generally include thrust repeated sections. One of the main points of interest was to examine the thermal maturity profile in the vicinity of fault contacts to see if lower levels of maturity were preserved below the thrusts. Previous work in the foothills and front ranges of southern Alberta (England and Bustin, 1986; Bustin and England, 1989; and Bustin, 1991) has indicated that thermal maturity in the overthrust blocks has been influenced by the emplacement of the overlying thrust sheets but that the underlying section has not returned to equilibrium in most cases. That is, the level of inferred maturation below the fault is lower than that of the section immediately above the fault (thermal maturation discontinuity or reversal).

An example of this phenomenon may be seen in the North Kootenay Pass well (4-23-5-5W5) where the overmature Rocky Mountain Group overlies the mature Fernie Group at about 5500 ft. (1675m). In this well the Mount Head Group (among others) is repeated twice below 5500 ft. but the level of thermal maturity of the lower occurrences falls on a relatively smoothly increasing maturity trend which, even at its maximum is below that of the overlying thrust slice. Bustin and England (1989) presented data for this same well (their figure 5) but did not interpret a trend line due to the scatter in their limited data points. Bustin and England measured vitrinite reflectance profiles and there may have been limited vitrinite available in many of the samples. On the other hand all of the maturation data presented here are based on Rock-Eval pyrolysis parameters which are available for any type of organic matter that is not highly overmature. It is important to note that, although there are multiple thrust faults interpreted in this well, there is only one instance where a Rock-Eval maturity reversal or discontinuity is visible. Additional maturity discontinuities may be present in the topmost section, but because Rock-Eval Tmax is not useful above about 500°C, they would not be visible even if they were present. The Waterton 7-34-3-1W5 well may be a similar example, with the topmost 2100 ft. (640m) appearing to be much higher in maturity than the rest of the well even though there are several stacked thrust

sheets below this depth. Again, the level of thermal maturity of the lower section of this well increases progressively across thrust faults.

In most of the wells represented in this study, there is no indication of any discontinuities in the thermal maturation profile. Examples include the Quirk 5-22-21-5W5 well which starts at a high level of maturity at the surface (near the end of the oil window) and increases to the point where Rock-Eval Tmax data is no longer sensitive, below about 4800 ft. (1460m) in this particular case. In other cases, such as Stimson 10-19-15-2W5, the maturity at surface is near the beginning of the oil window and progresses to fully mature at total depth (6600 ft. or 2000 m). The Ghost 10-13-26-8W5 well is fully mature at the surface and this increases smoothly through the oil window into overmaturity with increasing depth. The quantity and reactivity of residual organic matter in the Mount Head and deeper units are too low to yield a useful Tmax value.

The two Savanna Creek wells (9-31-12-4W5 and 15-32-13-4W5) are apparently very mature to overmature throughout the sampled intervals (600-4500 ft. [180-1370 m] and 400-2900m, respectively. The Rock-Eval Tmax parameter is very noisy at these high levels of maturity. The Salter "A" 1 3-17-15-4W5 well is also at high level of thermal maturity at the surface and this increases more or less progressively until the Tmax parameter is no longer useful. Similarly, the Gap Lake 6-4-24-7W5 well contains no useful Tmax data and is interpreted to be overmature.

### **Quantity of Organic Matter**

The total organic carbon (TOC) content ranges from several percent to zero depending on the rock unit and on the level of thermal maturity. The Kootenay and Fernie groups are consistently high in TOC (up to 10%) when they are not overmature. Other high TOC units include parts of the Belly River, Alberta and Blairmore groups as well as the Second White Specks and Blackstone Formation. These last two tend to have lower peak TOC values, rarely above 2.5%, but they are more consistent. This probably reflects the occurrence of intermittent coal or coaly deposits in the former and the marine shale nature of the latter.

It is important to note that even when the thermal maturity is quite advanced, several formations retain modest levels of TOC. Presumably these are capable of acting as sources for natural gas.

### **Type of Organic Matter**

The type of organic matter can be inferred from the Rock-Eval parameters Hydrogen Index (HI)and S2/S3 ratio. Because almost all of these data are from mature to overmature samples, the residual organic matter does not contain much pyrolyzable material (S2) and as a result both the HI and the S2/S3 ratio indicate that the quality of the kerogen is poor with respect to the generation of oil. Because both of these parameters are ratios with TOC and S3 in the

denominators respectively, care must be used in interpreting them because both parameters tend toward zero with increasing maturity.

In cases where the thermal maturity is moderate, both the HI and S<sub>2</sub>/S<sub>3</sub> values indicate that the Blackstone and Second White Specks contain Type II organic matter. Similarly, selected intervals within the coaly units display elevated HI and S<sub>2</sub>/S<sub>3</sub> ratios. For example, the Blackstone Formation has elevated values in the Racehorse (16-29-9-5W5) well while the Blairmore and Kootenay groups (along with the 'Jurassic shale') show high values in the Stimson (10-19-15-2W5) well.
