

MARGINAL NOTES
 This sheet of maps is one of three of similar format for the survey area. Grouped together are elements of certain affinities and/or similar distribution patterns. The three sheets are entitled:
 1) Base Metals and Pathfinder Elements (Open File 35874)
 2) Mafic Suite of Elements with Thorium and Lanthanum (Open File 35875)
 3) Alkali metals, Alkaline Earths, Manganese and Aluminum (Open File 35876)
 The elements depicted on these sheets are either those which show moderate geochemical data scatter in the survey area, or they are representative of a closely associated suite of elements (i.e. of the rare-earth elements, only La is shown because the distribution patterns of the other 7 determined [Ce, Eu, Lu, Nd, Sm, Tb, Yb] are almost identical). Listings of concentrations of these and other elements in each sample are given in the diskette released as Open File 35870. The diskette includes, also, a more detailed description of the methodology, analytical methods and analytical quality control.
 anomalies displaced down-ice from the mineralized source. Such factors need to be taken into consideration when interpreting geochemical results.

Reconnaissance Survey
 Lodgepole pine is the most common tree species in the Nechako area, and many metals concentrate in its outer bark. Hence, pine bark was selected as the sample medium for a reconnaissance-level biogeochemical survey in the Nechako project area. Samples were obtained by stripping approximately 100 g of outer bark from around the circumference of mature trees. The preferred sample interval was 2 m along roads, trails, and tracks. To minimize the effects of airborne contamination from roads, samples were collected at least 100 m into the forest. Along lesser used trails and tracks this distance was reduced to approximately 50 m. Within the survey area a two-person crew sampled trees at 268 sites within a 10-day period in late July 1997. Because of the lack of roads and trails in some areas, the sampling grid is not even. However, on average the sample coverage is approximately 1 site per 7 km².
 Bark samples were returned to the GSC laboratories in Ottawa where they were air-dried then reduced to ash by controlled ignition at 470°C for 24 hours. A separate split of dry material was ground to a powder and analyzed for mercury. Ash samples were submitted for the analysis of 58 elements by instrumental neutron activation (INAA) and 30 elements by inductively coupled plasma emission spectrometry (ICP-ES) at Activation Laboratories Ltd. (Ancaster, ON). The INAA analysis reports the total concentration of elements in the sample. The ICP-ES is performed on an aqua regia digest of the ash, and provides data on the total or near total concentrations of most elements. Data for some elements are obtained by both methods, but after review of the data from a quality control element only the more accurate and precise set of values is recorded in the data listing.
 The proportional dot maps are plotted using the Transverse Mercator projection, with a central meridian of 120°30' W. They were generated using A.M.E. (ARC/INFO Macro Language). The macro, with its corresponding input menu, prompts the user to input percentile break points and an appropriate scaling exponent for each element to be mapped. Proportional dots are then generated, using the ARC/INFO commands: POINTS, POINTS and SPOT commands, with the user specifying an appropriate minimum and maximum dot size. Exponents for individual elements were chosen to provide the best view of the analytical data. Accordingly, care should be exercised when attempting to compare different elements plotted with different exponents. Comments on distribution patterns are given in the digital file on the diskette available as Open File 35870.

Rationale for Biogeochemical Surveys
 The roots of a single large tree extract elements from many cubic metres of soil, overburden, groundwater and sometimes bedrock. These elements are then transferred to aerial parts of the tree where they may become locally concentrated. In a multi-disciplinary survey program, data derived from the analysis of an appropriate vegetation sample medium permits geochemical mapping, with enhanced background to anomalies, of certain elements, which assist both in mapping bedrock and in the search for concealed zones of mineralization. Because each species of plant has a different requirement for, and tolerance to, a range of chemical elements, some partitioning of elements takes place and there is selective absorption and transference into the plants. For biogeochemical exploration, conifers provide suitable and effective sample media because they are pioneer plants that have a wide tolerance to many trace elements. The outer bark is a repository for many elements that are not required for the metabolic function of the tree.
 The geochemical information supplied by vegetation is different from that of soil. Just as two methods of geochemical survey may provide different information, so may two methods of geochemical survey. A high correlation between distribution patterns of two geochemical sample media is the exception rather than the rule. In geological environments there may be sufficient concentrations of metals to form a mineral deposit, such as "critical mass" of elements may be sufficient to generate biogeochemical anomalies above the mineral source (due to leached effluents) or closer to it (due to groundwater movement or upward movement in electrochemical cells). Tills, however, usually have geochemical
