ABSTRACT

The Geological Survey of Canada investigated four kimberlite pipes in the Kirkland Lake area, northeastern Ontario to document indicator signatures in glacial sediments. This report focuses on results from the C14 kimberlite in Clifford Township. The kimberlite has been eroded down by preglacial and glacial weathering to a level approximately 20 to 30 m below the surrounding bedrock. The subcropping surface consists of heterolithic tuffisitic kimberlite breccia. Kimberlite indicator minerals of the C14 pipe are dominated by Cr-pyrope and chromite (\pm Cr-diopside) derived from lherzolitic xenoliths with only a minor proportion from harzburgite and dunite sources. No evidence of eclogitic xenoliths in the C14 kimberlite were found in this study. The low numbers of Cr-poor pyrope, diopside and Mg-ilmenite point to a low contribution from the Cr-poor megacryst suite which can be dominant in other kimberlites in the Kirkland Lake kimberlite field. The presence of subcalcic garnet and Cr-rich and (magnesio-) chromite suggests a moderate diamond potential for the C14 pipe. The relative abundance of indicator minerals in the C14 kimberlite, listed in decreasing order of abundance, is: pyrope > Cr-diopside > chromite > Mg-ilmenite. These relative abundances are mimicked in till overlying and just down-ice of the kimberlite. Indicator mineral chemistry for grains recovered from the glacial sediments around the C14 kimberlite are also similar to that for the kimberlite. Kimberlite samples from the C14 pipe contain tens of thousands of indicator mineral grains in 10-kg. Incorporation of kimberlite into the till is obvious overlying the C14 kimberlite and just down-ice and is reflected in all size fractions of till. The non-ferromagnetic heavy mineral fraction (coarse to fine sand) of till contains anomalous concentrations of indicator minerals (tens to thousands of grains) and displays elevated concentrations of Cr, Sr, Ta, La, Ce, and Eu. The <0.063 mm (silt+clay) fraction has elevated concentrations of Ba, Co, Cr, Tot Fe, K, Mg, Ni, Sr and Ti and the pebble sized-fraction contains several kimberlite clasts.

INTRODUCTION

In 1992, the Geological Survey of Canada (GSC) began a five-year project to investigate known kimberlites in the Kirkland Lake area, northeastern Ontario. The purpose of the project was to document glacial dispersal patterns and indicator signatures associated with known kimberlite intrusions as well as regional indicator mineral patterns in glacial sediments collected across the area.

Most bedrock in the Kirkland Lake area is covered by glacial sediments that are a few metres to 100 m thick. Kimberlite, being relatively soft, was differentially eroded by preglacial weathering and glacial erosion such that it subcrops 10 to 35 m below the surrounding bedrock. Because of this deep erosion, all kimberlite pipes in the area are covered by thick sequences of glacial sediment and have no surface expression. By applying a combination of indicator mineral and geophysical methods, several kimberlite pipes and dykes (Fig. 1) have been discovered in the region within the last 15 years (Brummer et al., 1992a; McClenaghan, 1993; Zalnierius and Sage, 1995; Sage, 1996).

The C14, B30, A4 and Diamond Lake kimberlite pipes and the Buffonta kimberlite dyke (Fig. 1) have been examined to document kimberlite composition, glacial dispersal patterns, down-hole geophysical signatures and surficial geochemical signatures (McClennaghan et al., 1996, 1998; McClennaghan, 1996a, b). These kimberlites were chosen in order to examine glacial dispersal patterns in tills (C14, B30, A4, Buffonta) and in glaciofluvial esker sediments (Diamond Lake). Thirty-one overburden holes were drilled by the GSC around the four kimberlite pipes in the winter of 1993. Soil and vegetation samples were collected over the C14 and Diamond Lake pipes to examine surficial signatures associated with the pipes (McClennaghan et al., 1995; McClennaghan and Dunn, 1995; Dunn and McClennaghan, 1996). Down-

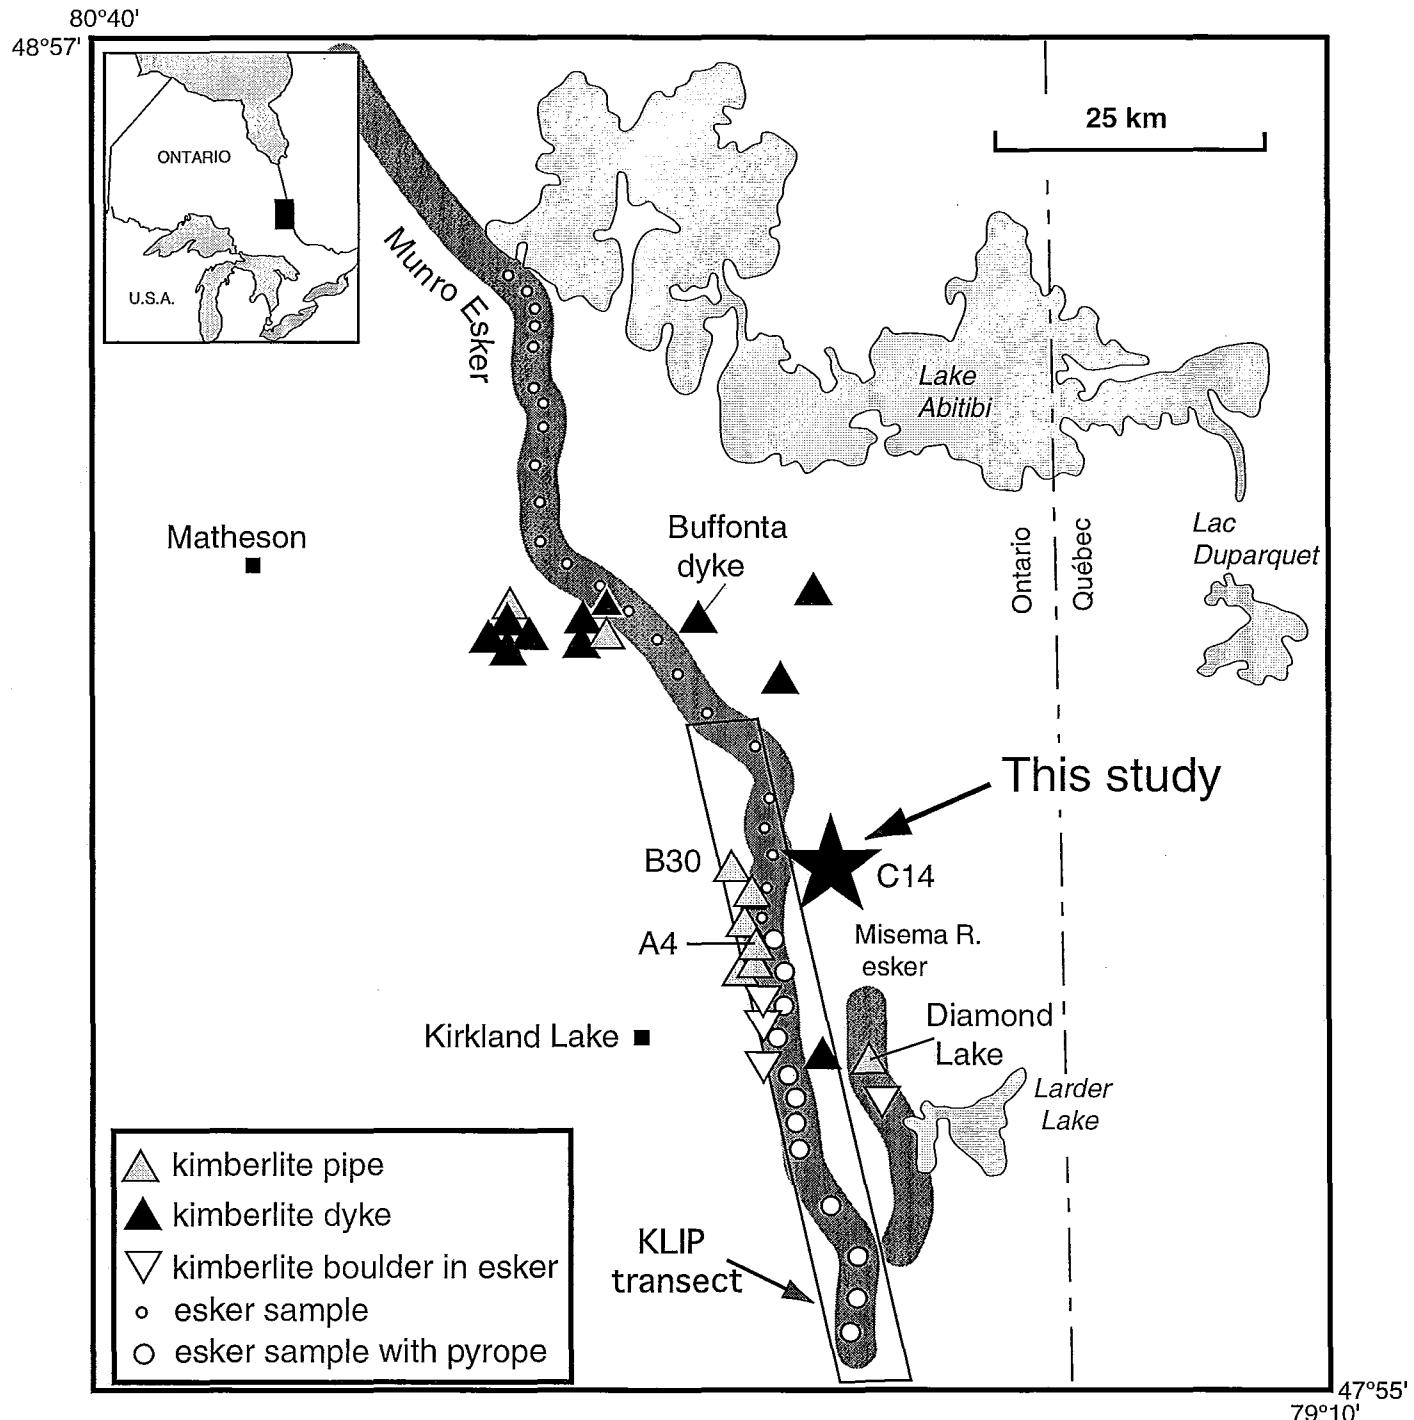

Figure 1. Location of kimberlite intrusions and kimberlite boulders and pyrope found in eskers (kimberlite locations from Zalnieriunas and Sage, 1995; kimberlite boulder locations from McClenaghan, 1993; esker sample data from Lee, 1965).

hole logging was used to document the geophysical character of kimberlites and the glacial sediments overlying them. Sediments and vegetation were also collected over the Buffonta kimberlite dyke to compare the signatures from a small hypabyssal kimberlite intrusion to those of much larger pipes (McClenaghan et al., 1995; McClenaghan and Dunn, 1995; Dunn and McClenaghan, 1996). This report describes results for samples collected around the C14 kimberlite.

Location and access

The Kirkland Lake kimberlite field is in northeastern Ontario, north and east of Kirkland Lake and 100 km southeast of Timmins (Fig. 1). The C14 kimberlite pipe is located in topographic map NTS 32D/5 at 48°17'N and 79°48'W, (UTM Zone 17, 588990, 5348150,) at the southern edge of Clifford Township, approximately 20 km northeast of Kirkland Lake. The property is accessed by a logging road extending east from Highway 672. The Misema River, just southeast of the kimberlite, flows southwest into Kennedy Lake (Fig. 2).

Geology

The Kirkland Lake area is one of several important gold camps in the Abitibi Greenstone Belt of eastern Canada. The Abitibi Belt consists of Archean metavolcanic, metasedimentary and intrusive rocks. At the time of kimberlite emplacement during the Late Jurassic, the Archean rocks were overlain by an estimated 700 m of Devonian to Ordovician carbonate rocks (Armstrong and McCracken, 1996). The C14 kimberlite intruded Archean metavolcanic rocks (Fig. 2) and Paleozoic carbonate rocks approximately 156 Ma ago (Brummer et al., 1992b). During the last 150 million years, the Paleozoic rocks and the upper part of the kimberlite have been eroded away with diatreme facies kimberlite occurring at the present erosion level (Fig. 3). The subcropping surface of the kimberlite is approximately 200 m by 300 m.

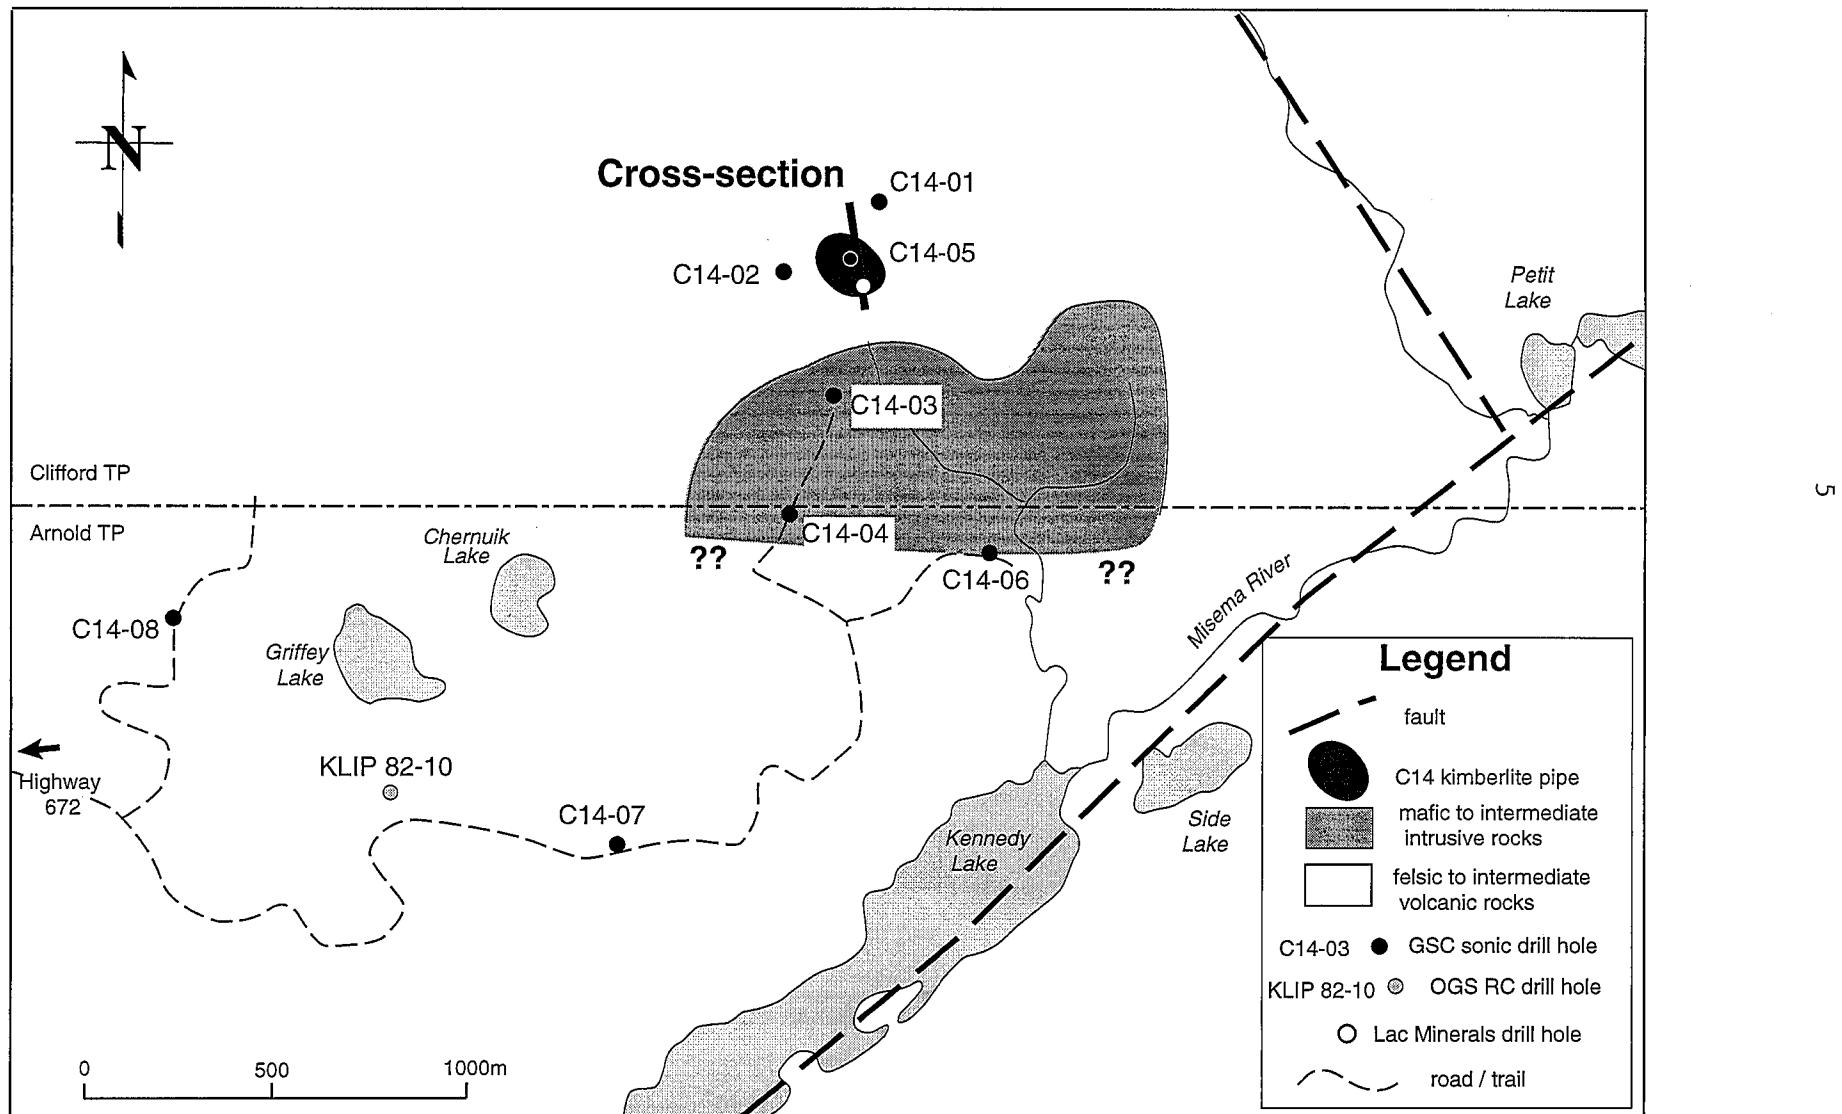

Figure 2. Bedrock geology and location of the C14 kimberlite pipe and drill holes.
Geology from Jensen (1975) and Hogg (1964).

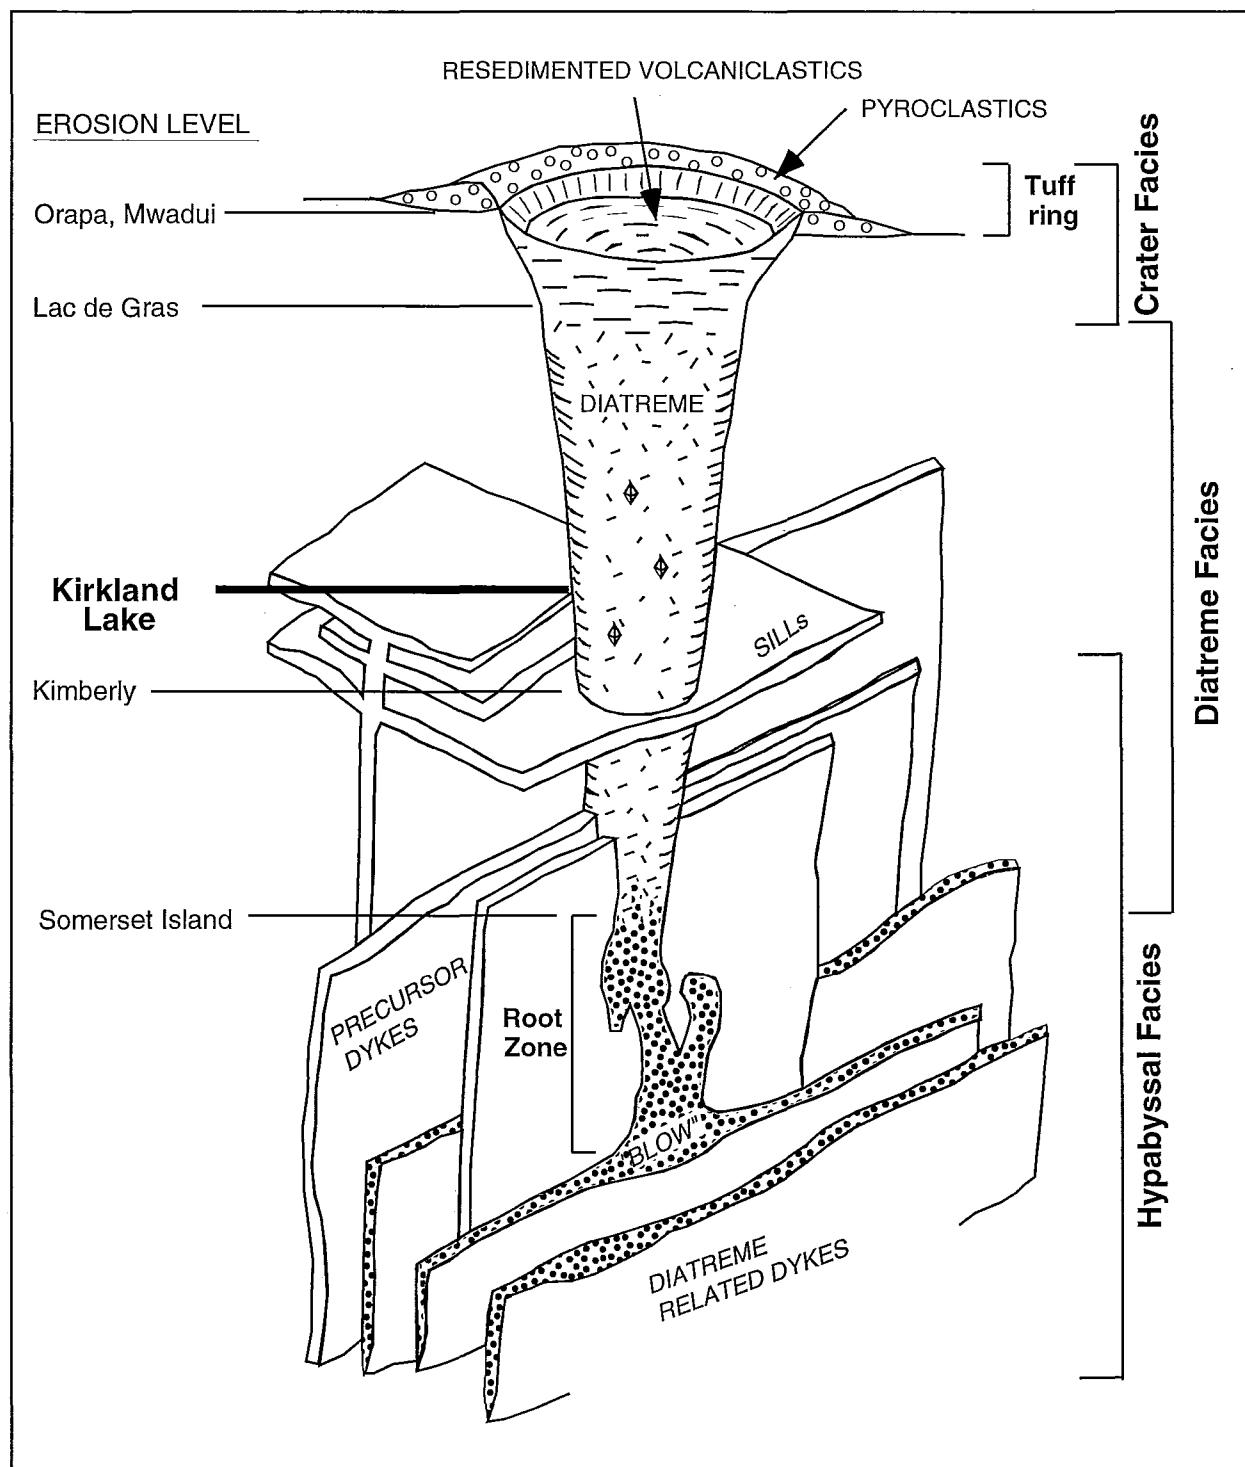

Figure 3. Model of a kimberlite (from Mitchell, 1986) showing present day erosion levels for kimberlites in Kirkland Lake and elsewhere (from Kjarsgaard, 1996).

The rocks are classified as heterolithic tuffisitic kimberlite breccia with pelletal textured groundmass (Photo 1) (for additional photos see Brummer et al., 1992b, p. 362). The kimberlite groundmass consists of serpentine, phlogopite, chlorite and calcite and is dark greenish-grey. Crustal xenoliths (variable, but >20 modal %) of greenish-grey to white Paleozoic limestone fragments are common throughout, ranging in size from 1 cm to 1 m. These wall rocks have been incorporated into the intruding kimberlite magma and drawn down into the pipe below the contact with Archean rocks. Today, the nearest Paleozoic rocks are 300 km north and 80 km south of the kimberlite pipe (Ontario Geological Survey, 1991). Several gem quality microdiamonds have been recovered from the C14 kimberlite (Fipke, 1990; Brummer, 1992b). A 17.55 tonne kimberlite sample yielded 8 macrodiamonds, weighing a total of 0.30 carats, that have good color and clarity (for photos see Brummer 1992b, p. 364). The largest diamond weighed 0.17 carats. The kimberlite has a strong positive magnetic signature (Brummer, 1992b; MacFadyen, 1993; Keating, 1995, 1996) that forms a distinct bulls eye response on airborne magnetic survey maps (Fig. 4) published by the Ontario Geological Survey (Ontario Geological Survey, 1979) and by the Geological Survey of Canada (Geological Survey of Canada, 1993).

The Kirkland Lake region was covered by the Laurentide Ice Sheet during the Wisconsinan which deposited a silty sand till, known locally as Matheson Till (Baker, 1985). Ice flowed west to southwest during the main phase of glaciation (Fig. 5), then south and finally southeast during deglaciation (McClenaghan et al., 1995; Veillette and McClenaghan, 1996). As the glacier retreated northward approximately 10,000 years ago, glacial Lake Ojibway fronted the ice sheet and thick sequences of fine grained glaciolacustrine sediments were deposited over top of the till and bedrock (Baker, 1985). The C14 pipe is covered by Matheson Till, which is in turn overlain by interbedded sand and till. These sediments are overlain by a thick sequence of

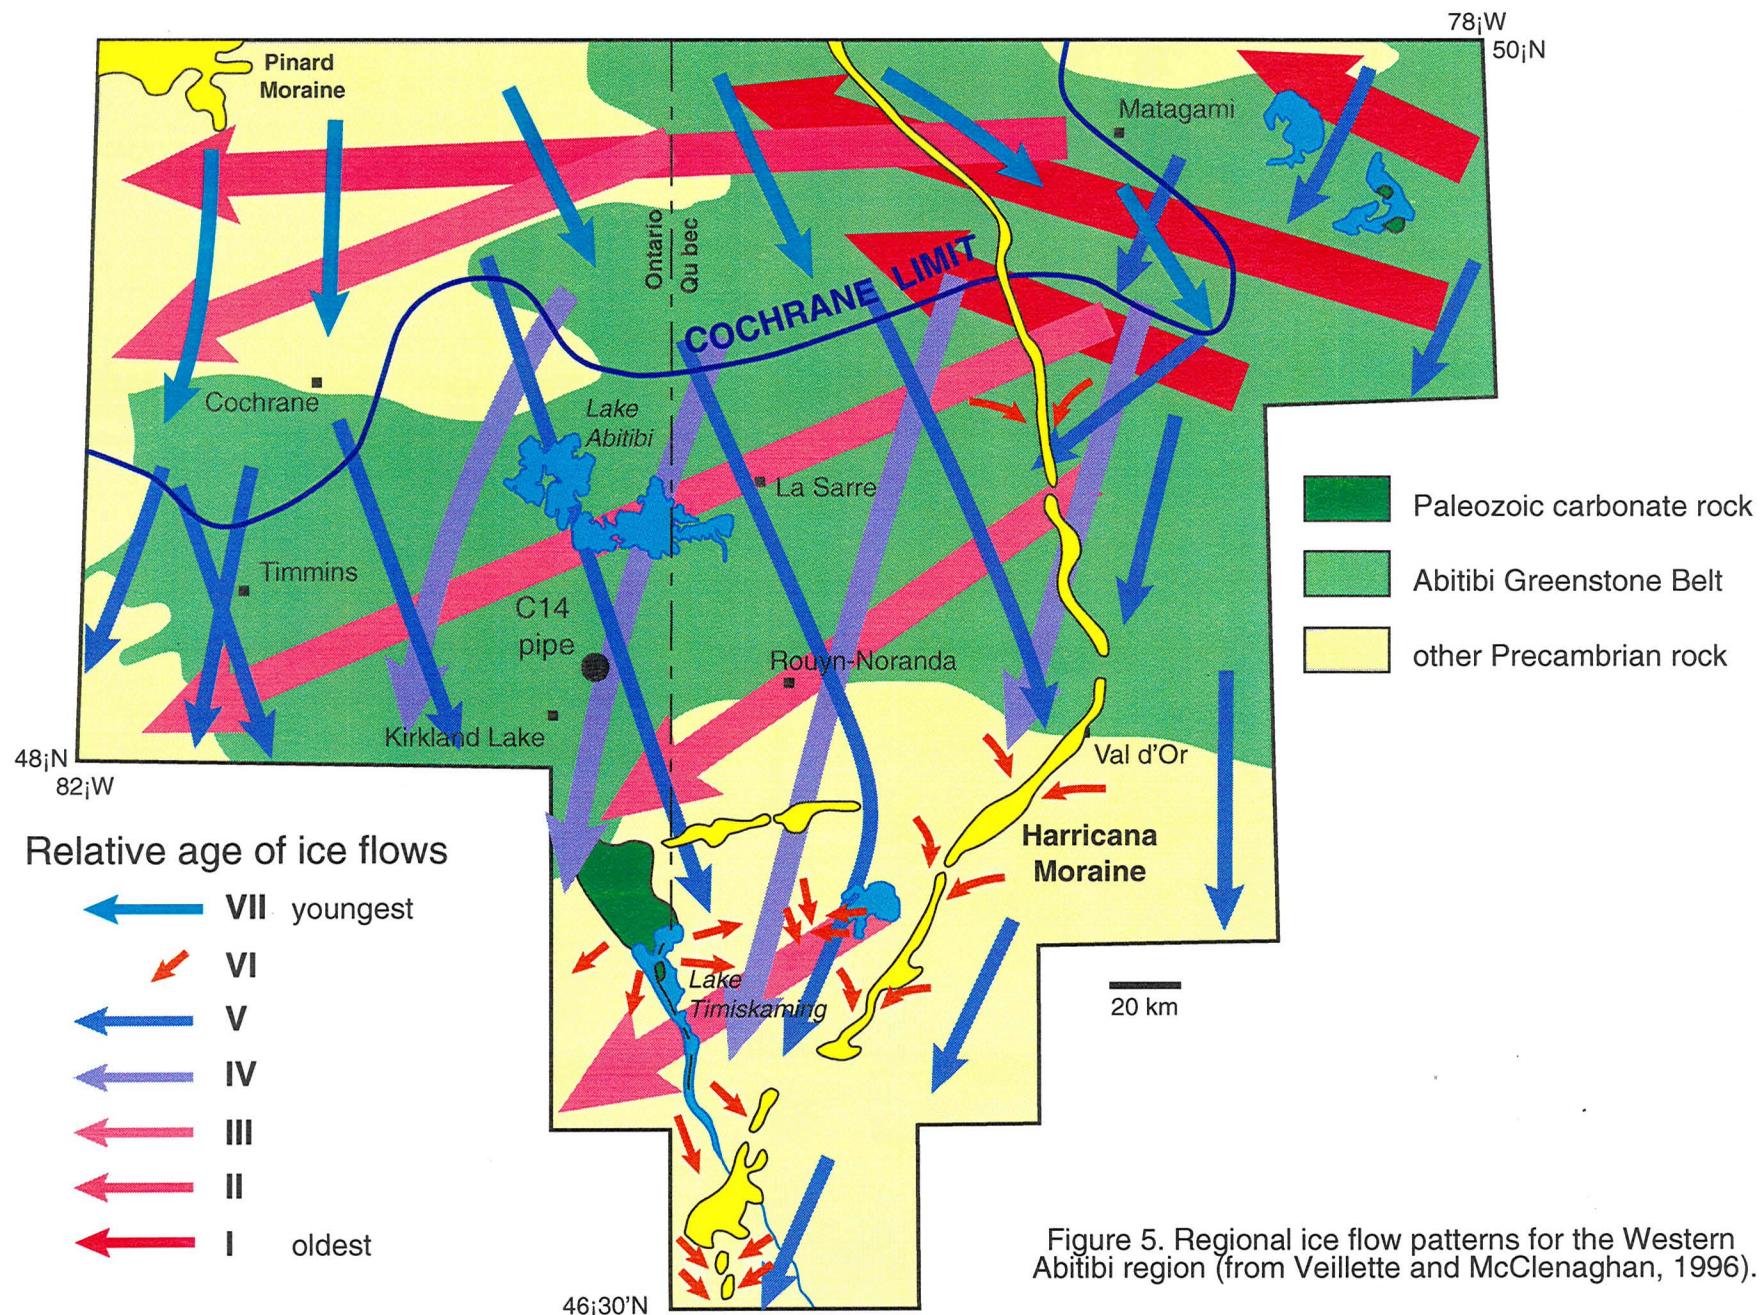

Figure 5. Regional ice flow patterns for the Western Abitibi region (from Veillette and McClenaghan, 1996).

fine-grained glaciolacustrine sediments and capped by 1 to 2 m of aeolian sand and 0.5 to 1 m of organic material. Glacial sediments are thickest directly over the kimberlite which has been differentially eroded to a maximum of 30 m below the adjacent bedrock (Fig. 6) due to preglacial weathering and by glacial and glaciofluvial erosion. Bedrock outcrops just 100 m south of the kimberlite and is common throughout the area surrounding the C14 pipe (Fig. 7). The surface between bedrock outcrops is covered by thick glacial sediments capped by aeolian sand deposited after deglaciation but prior to the establishment of vegetation. Parabolic dunes on surface are common in the area just west of the C14 kimberlite (Baker et al., 1982).

Regional kimberlite exploration

Kimberlite in the Kirkland Lake region was first reported by Satterly in 1949, 35 km north of Kirkland Lake (Satterly, 1949; Brummer et al., 1992a). While studying gold grains in esker sediments, Lee (1965) discovered pyrope garnets in sand along a 120 km segment of the Munro Esker near Kirkland Lake (Fig.1). Lee's elevated pyrope concentrations correspond to the area where several kimberlites pipes were subsequently discovered 20 years later (Fig. 8a). A kimberlite dyke was then discovered 15 km east of Kirkland Lake, in the Upper Canada Gold Mine (Lee, 1968; Lee and Lawrence, 1968). Since that time, several hundred kimberlite boulders have been found in gravel pits in the Munro and Misema River eskers (Fig. 1) (Baker, 1982; Brummer et al., 1992a; McClenaghan, 1993).

Between 1979 and 1982 and prior to the discovery of kimberlite pipes in the region, the Ontario Geological Survey (OGS) sampled till in 171 reverse circulation overburden holes and 200 backhoe pits in the Kirkland Lake region as part of the Kirkland Lake Initiatives Program (KLIP), directed mainly at gold exploration (Fortescue et al., 1984). Pyrope and Cr-diopside were recognized in glacial sediments recovered at several KLIP sites (Averill

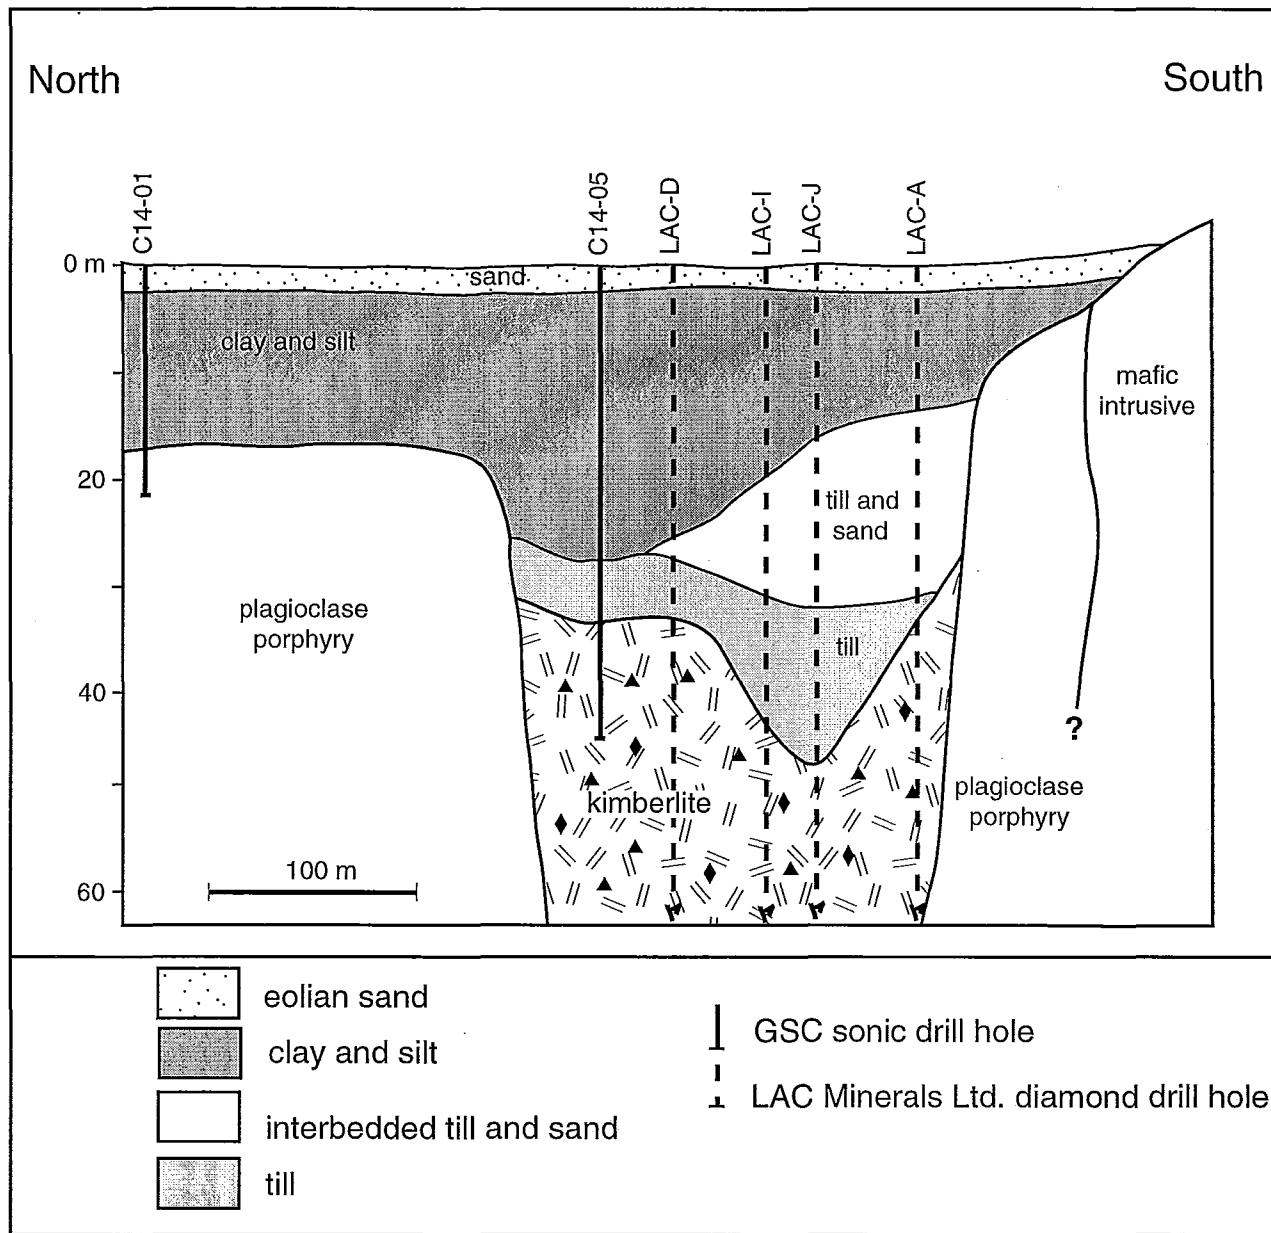

Figure 6. Schematic north-south cross-section over the C14 kimberlite showing glacial stratigraphy and sediment thickness.

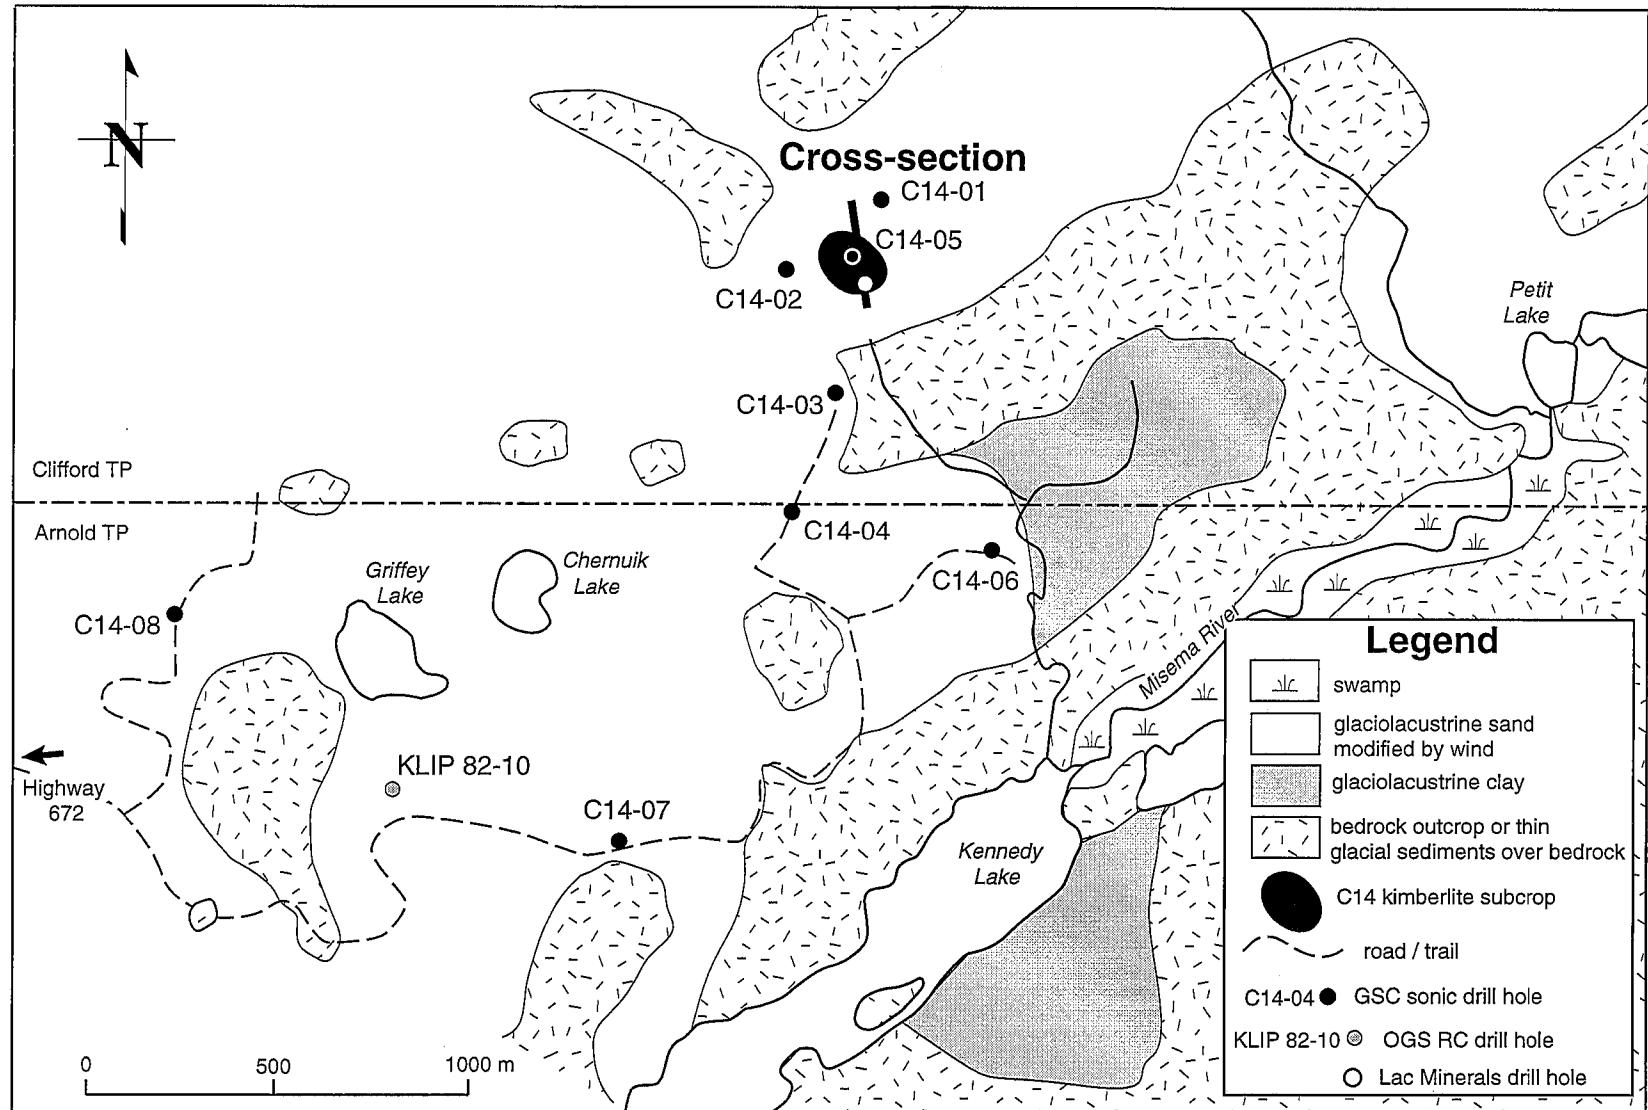

Figure 7. Surficial geology of the C14 kimberlite area and locations of GSC, OGS and LAC Minerals drill holes (geology from Baker et al., 1982).

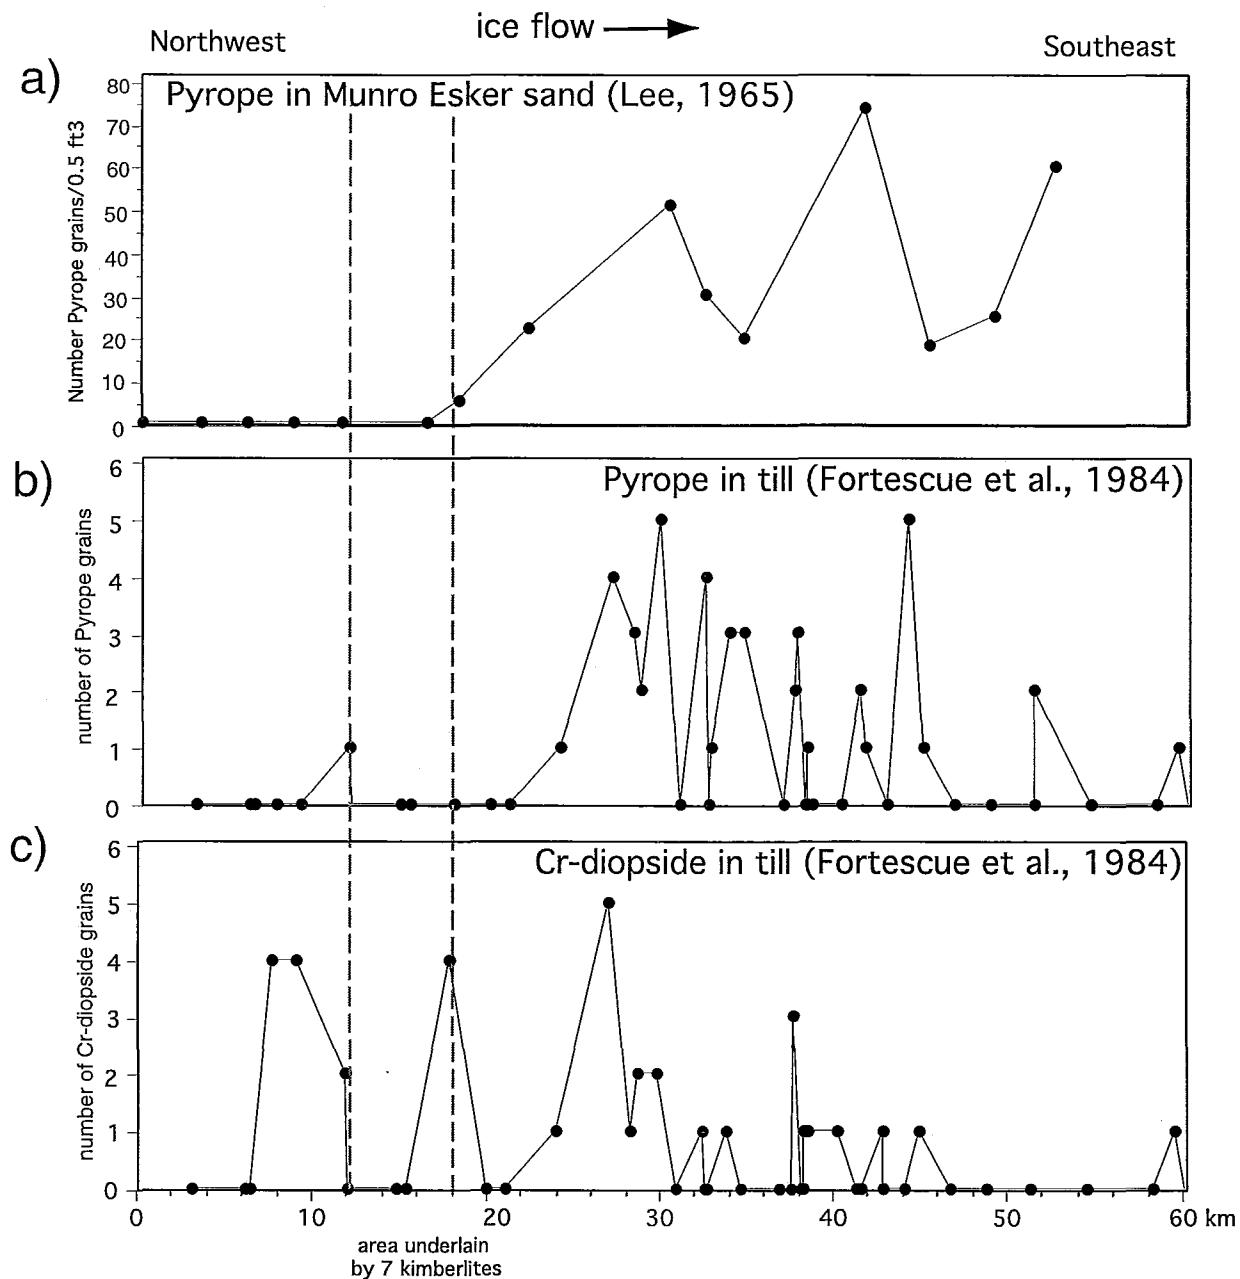

Figure 8 a) Abundance of pyrope in 0.5 ft³ of sand along the Munro Esker (Lee, 1965); b) pyrope and c) Cr-diopside concentration in a 1/4 split of the heavy mineral fraction of till samples along a northwest-southeast transect through the KLIP study area, Kirkland Lake (from Fortescue et al., 1984, p. 416-424). See Figure 1 for location of the Munro Esker sample sites and the KLIP sample transect.

and Fortescue, 1983; Fortescue et al., 1984) and this information aided in the discovery of several kimberlites near Kirkland Lake (Pegg et al., 1990; Brummer et al., 1992a,b). Pyrope abundance in KLIP till samples (Table 1) along a northwest-southeast transect (Fig. 1) displays a similar dispersal pattern (Fig. 8b) to pyrope in the Munro Esker sediments documented by Lee (1965) some 20 years earlier. In both studies, pyrope appears in glacial sediments in the same general area (subsequently found to contain seven kimberlite pipes) and its presence continues for another 30 to 40 km down-ice. Cr-diopside in till (Fig. *c), displays a similar pattern but continues for only 25 km down-ice. Remarkably, these data were published before kimberlite pipes were discovered in Kirkland Lake.

Some KLIP sites drilled in 1982 south and southwest of the C14 kimberlite contained pyrope and Cr-diopside and their presence combined with a strong airborne geophysical anomaly indicated by the OGS magnetic survey (Ontario Geological Survey, 1979), aided in the discovery of the C14 kimberlite in 1985 (Fipke et al., 1989; Pegg et al., 1990; Brummer, 1992a). To date, at least 11 kimberlite pipes and several dykes (Fig. 1) have been found in the Kirkland Lake area and several more in the New Liskeard area, 70 km south (Brummer et al., 1992b; Zalnierius and Sage, 1995; Sage, 1996).

Previous kimberlite research in the Kirkland Lake area

Much work has been completed on the Kirkland Lake kimberlites in recent years. Schulze (1993a, 1993b, 1995, 1996a, 1996b), Schulze and Anderson (1994), Schulze et al. (1995), Vicker and Schulze (1994), Meyer et al. (1994), Sage (1996), Armstrong et al. (1997), and Vicker (1997) have examined mineral chemistry of garnets, diopsides, ilmenites, and spinels from the C14 kimberlite. Down-hole logging was carried out by the GSC on GSC overburden drill holes and a few LAC Minerals diamond drill holes in the winter of 1993 to document the geophysical character of kimberlites and

overlying sediments (Douma, 1995; Mwenifumbo et al., 1993; Mwenifumbo et al., 1996).

McClenaghan et al. (1993) chemically analyzed indicator minerals from archived heavy mineral concentrates from several KLIP holes to confirm the visual identification of kimberlite indicator minerals and to look for undetected indicator minerals. Archived concentrates from the Ontario Geological Survey Black River-Matheson (BRIM) regional till sampling project, immediately north of the KLIP area, were also examined to evaluate the potential for finding additional kimberlites north of the known kimberlite cluster. Several BRIM samples were found to contain elevated concentrations of Cr-pyrope, Cr-diopsid and Mg-ilmenite that warrant further investigation. Averill and McClenaghan (1994) described indicator mineral abundance, size and shape down-ice from the C14 and Diamond Lake kimberlite pipes. They documented the ilmenite-poor nature of the C14 pipe and the southwest glacial dispersal of pyrope, Cr-diopsid and chromite. Studies of indicator mineral and geochemical signatures of other kimberlites and associated glacial sediments in the Kirkland Lake area include the B30 kimberlite (McClenaghan et al., 1996) and the Diamond Lake kimberlite (McClenaghan et al., 1998).

METHODS

Sample collection

Sediments at eight sites around the C14 kimberlite were cored by the GSC during the winter of 1993 (Fig. 2). Hole C14-02 was drilled 30 m west of the kimberlite and holes C14-03, 04, 06 to 08 were drilled south of the kimberlite to test for dispersal down-ice. Hole C14-01 was drilled 40 m north of the kimberlite to determine regional background values of indicator minerals. Hole C14-05 was drilled directly into the body to document local (few metres) glacial dispersal and to sample kimberlite. Holes were drilled by JR Drilling

Ltd., Hadashville, Manitoba using a rotasonic, more commonly known as sonic, drill that provides 9 cm diameter, continuous core of sediments and bedrock. Approximately 2 m of bedrock were cored at the bottom of holes north and south of the kimberlite and 10 m of bedrock were cored in the kimberlite. Overall drilling costs averaged \$100 per metre for the drilling program. All sonic drill core was boxed on site and taken to the Ontario Ministry of Northern Development and Mines Drill Core Library in Swastika. There, all core was split length wise, logged and photographed. Samples, weighing between 4 and 25 kg were collected for recovery of kimberlite indicator minerals and gold grains. From the eight sites around the C14 kimberlite, 31 samples of till, sand and gravel (samples 93MPB001 to 025, and 048 to 052) were collected over 2 to 4 m intervals. Typically, a 10-kg sample is collected for gold and base metal exploration programs in the region, however, larger samples (up to 25-kg) were collected in this study to determine appropriate sample sizes for indicator mineral counting. Two 17-kg samples of kimberlite (93MPB204 and 205) were collected from hole C14-05 to determine geochemical and mineralogical characteristics of kimberlite for comparison to glacial sediments. A 500 g sample (Fig. 9) was collected from the same intervals as the bulk samples, for geochemical analyses of the fine fraction (<0.063 mm), textural (% sand, silt clay), chittick carbonate (% calcite and dolomite) and some clay mineralogical analyses of the <0.063 mm fraction. Samples were not collected from hole C14-07 because no till, sand or gravel were intersected. Glaciolacustrine silt was sampled in hole C14-05 for geochemical, textural and carbonate analyses to investigate the usefulness of this sampling medium in kimberlite exploration. Drill logs, sample intervals and core descriptions are included in Appendix A.

Kimberlite bedrock from hole C14-05 was logged and sampled by B.A. Kjarsgaard (GSC). Archean bedrock from the other seven sonic drill holes

was logged and sampled by B.R. Berger (Ontario Geological Survey). Selected samples were collected for thin sections and geochemical analyses.

Sample preparation

Glacial sediment and kimberlite samples were processed by Overburden Drilling Management Ltd., Nepean, Ontario, to recover heavy mineral concentrates for geochemical analysis and for examination of kimberlite indicator minerals and gold grains (Sample A- Fig. 9). Kimberlite samples were soaked in water for 3 days prior to processing but were not subjected to any mechanical crushing. Weights for all sample fractions produced during the processing procedure are reported in Appendix B. The >2 mm (+10 mesh) material was screened and retained for pebble lithology classification. The <2 mm fraction was then screened to obtain two separate size fractions: 1) 1.0 to 2.0 mm fraction, and 2) <1.0 mm fraction.

1) The 1.0 to 2.0 mm fraction was not preconcentrated on the shaking table because of the risk of significant losses of coarse heavy minerals. Instead, this fraction was taken directly to methylene iodide (MI) diluted with acetone to a specific gravity (S.G.) of 3.2 to separate the light and heavy mineral fractions.

Methylene iodide was diluted from full strength (S.G. 3.3) to maximize the recovery of Cr-diopside (S.G. \geq 3.2), the kimberlite indicator mineral with the lowest specific gravity. The light minerals (<3.2 S.G.) were removed and put aside for future reference. The heavy mineral (>3.2 S.G.) split was further refined by removing the ferromagnetic minerals using a hand magnet, to produce a 1.0 to 2.0 mm non-ferromagnetic heavy mineral fraction.

2) The <1.0 mm fraction was processed using a combination of tabling and heavy liquid separation. First, the <1.0 mm material was passed over a shaking table twice to obtain a preconcentrate, which was then panned to recover gold grains. The gold grains were counted, described and returned to

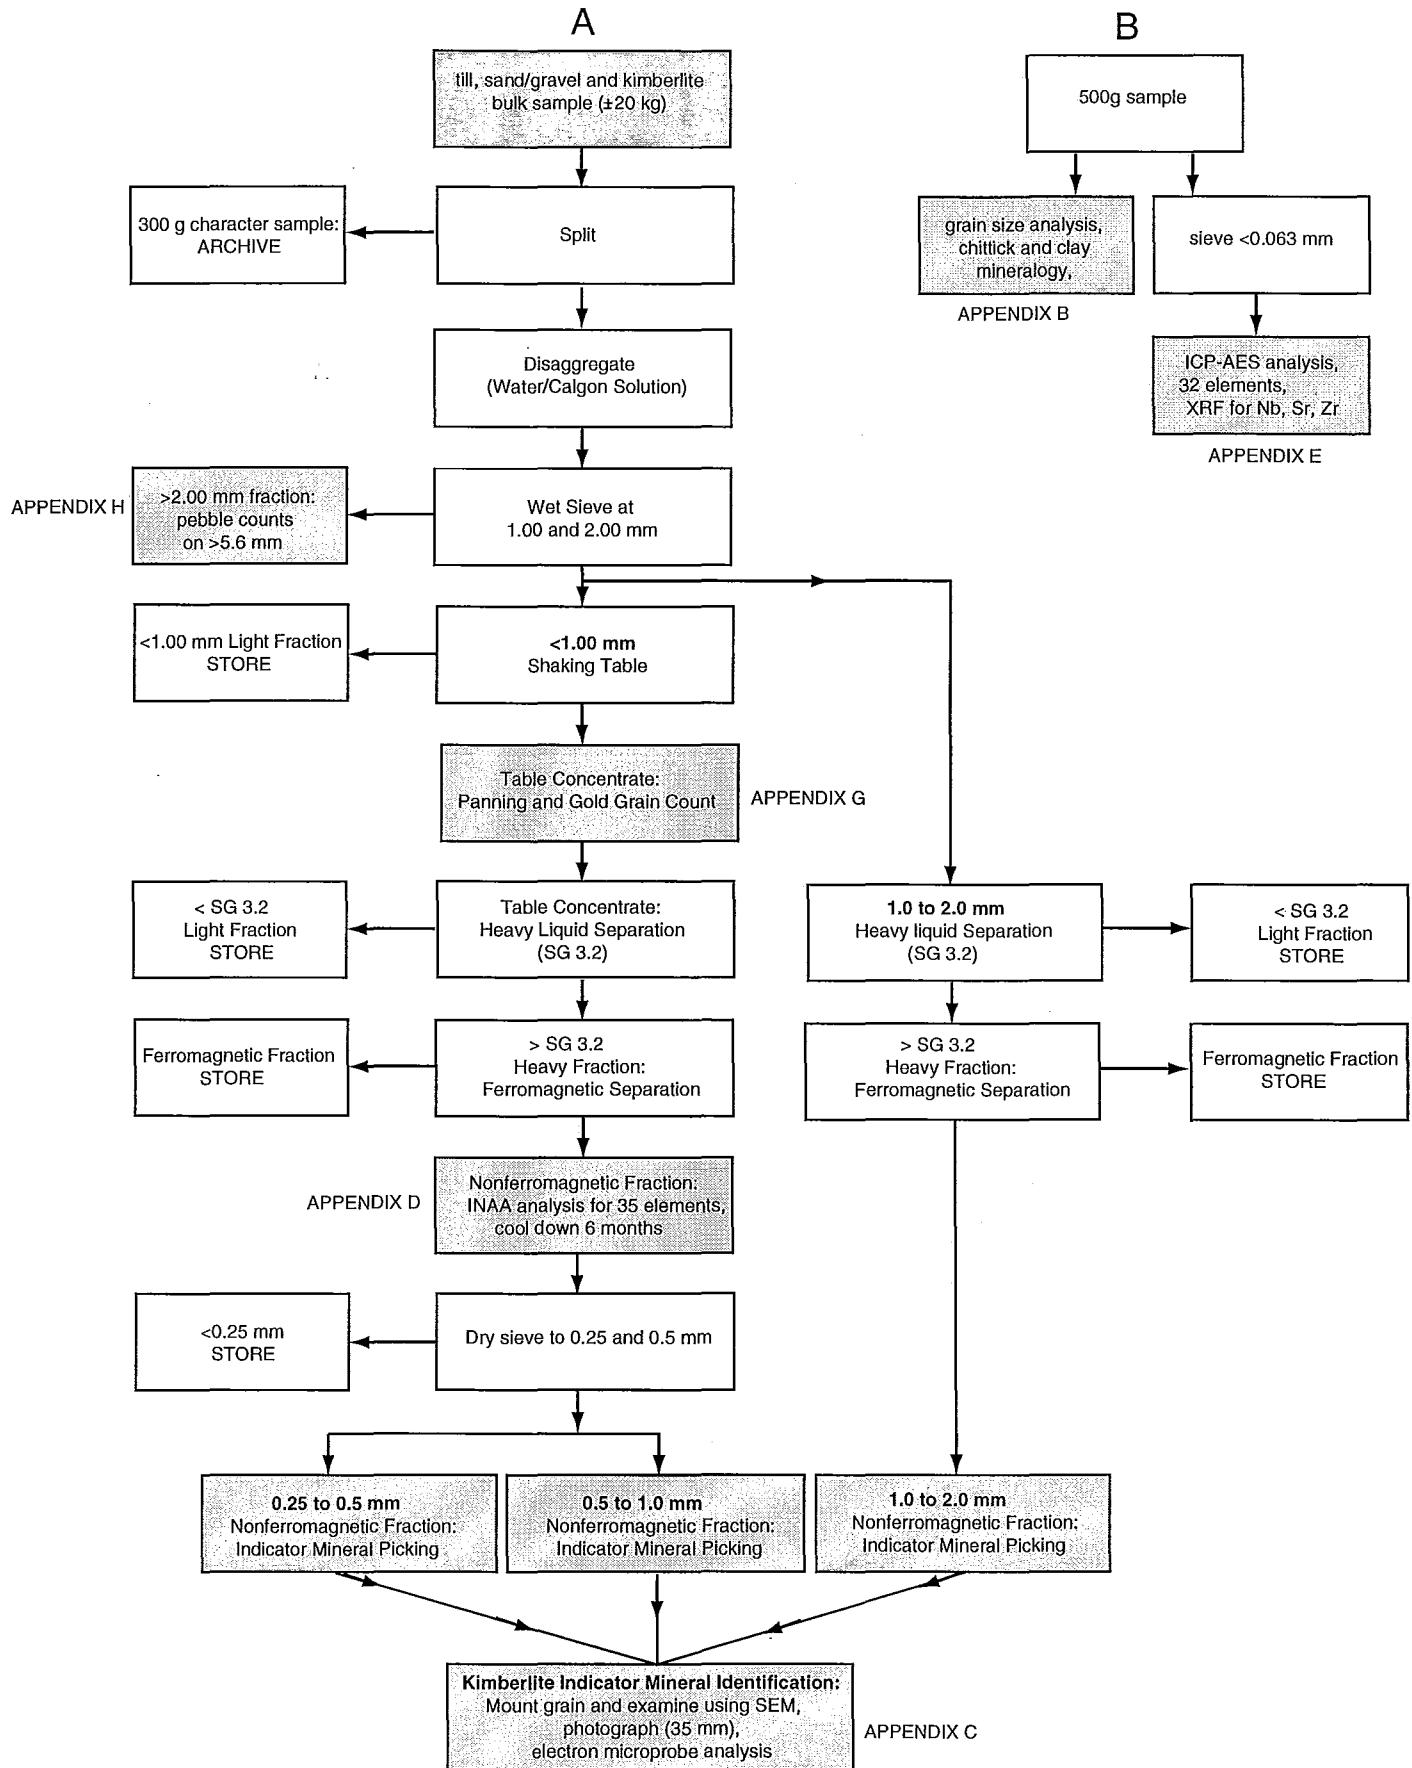

Figure 9. Sample processing flow sheet for kimberlite and glacial sediment samples: A) recovery of kimberlite indicator minerals and gold grains; and B) fine fraction geochemistry. Shaded boxes correspond to data listed in appendices.

the sample. The preconcentrate was then further refined using heavy liquid separation, as described above, to produce a heavy mineral fraction (S.G.>3.2). The ferromagnetic heavy minerals were removed using a hand magnet, leaving a <1.0 mm non-ferromagnetic heavy mineral fraction for picking. This combination of tabling and heavy liquid separation was used to recover indicator minerals because tabling also recovers gold grains that can be examined and counted.

Kimberlite indicator mineral identification

Non-ferromagnetic heavy mineral concentrates were sent to Lakefield Research, Lakefield, Ontario or Overburden Drilling Management Ltd. for indicator mineral picking and mounting. The <1.0 mm concentrates were sieved into three fractions: <0.25 mm (-60 mesh), 0.25 to 0.5 mm and 0.5 to 1.0 mm. The <0.25 mm fraction was set aside. The 0.25 to 0.5 mm and 0.5 to 1.0 mm fractions and the already prepared 1.0 to 2.0 mm fraction were then examined using a binocular microscope and potential kimberlite indicator minerals were removed. Indicator minerals were identified on the basis of visual properties, such as colour, grain morphology and the presence of adhering kimberlite matrix material. Minerals picked included Cr-pyrope (purple, ± kelyphite rims), Ti-Cr-pyrope (orange-red to deep red), Cr-diopside (emerald green), Mg-ilmenite (metallic black with conchoidal fractures on broken surfaces, unbroken grains appear as irregular to rounded black grains with grey/white coatings, perovskite overgrowths), and chromite and other Cr-spinel (black with reddish- brown edges, octahedral crystal shape to irregular shaped grains). Picked grains were mounted in 25 mm epoxy mounts and polished in preparation for electron microprobe analysis.

Electron microprobe analyses were carried out at the GSC using operating conditions similar to those described by McClenaghan et al. (1996), and Stirling and Pringle (1996). Analyses were completed using a four

spectrometer Cameca SX50 electron microprobe and all grains were analyzed using the "GARNET" routine. This routine was developed by the GSC to analyze for the major elements required to identify the potential mineral species using a minimum of probe time. The raw data were processed with the Cameca PAP program (Pouchou and Pichoir, 1984). The dead time correction formula (Willis, 1993) has been changed for the SX50 to achieve linearity at higher count rates. The standards and operating conditions are given in Appendix C-Table 1 and calculated detection limits and counting times are given in Appendix C-Table 2. Microprobe analyses are included in Appendix C.1 (digital data file only, on diskette accompanying this report). Subsets of the microprobe analyses for those minerals identified as kimberlite indicator minerals are listed in Appendix C.2 to C.6.

Microprobe data were sorted by chemical composition and the grains were labeled with mineral names. For minerals and mineral groups that form solid solution series, theoretical endmembers compositions (LeMaitre, 1982, Table A13) were used to calculate threshold values (at approximately 50:50 mol %) for individual members of binary solid solution series. These threshold values are shown in Table 2. For minerals that contain substantial amounts of more than two endmembers (which is the case for most garnets and spinels), the threshold values were lowered accordingly (<50 mol % of one endmember). In equivocal cases, molar fractions of the critical oxides were calculated in order to assess the endmember with the highest (name giving) proportion. Other minerals were identified by comparing wt. % oxides to published analyses (Deer et al., 1978). Mineral names of grains with low totals were set in brackets. Prefixes were added to some of the indicator mineral names to emphasize elevated contents of petrogenetically critical elements such as Mg, Cr, and Ti which are important in distinguishing between potential kimberlite minerals and those from other bedrock sources. Threshold values for these prefixes (see Table 2) were chosen arbitrarily and

might differ from those used by other authors. Readers are encouraged to examine the microprobe data and reclassify indicator minerals using their own criteria.

Table 2. Classification criteria for identifying minerals.

| | <u>Criteria</u> | <u>Mineral name</u> |
|-------------|--|-------------------------------|
| Al-garnet | > 21 wt.% MnO = | Spessartine |
| Al-garnet | > 13 wt.% MgO = | Pyrope |
| Al-garnet | > 17 wt.% CaO = | Grossular |
| Garnet | < 11 wt.% Al ₂ O ₃ & >13 wt.% CaO = | Andradite |
| Garnet | > 15 wt.% Cr ₂ O ₃ &>17 wt.% CaO = | Uvarovite |
| Andradite | > 2 wt.% Cr ₂ O ₃ = | Cr-Andradite |
| Andradite | > 5 wt.% MgO = | Serpentinized (Cr-) andradite |
| Pyrope | > 2 wt.% Cr ₂ O ₃ = | Cr-Pyrope |
| Diopside | >0.5 wt.% Cr ₂ O ₃ = | Cr-Diopside |
| Cr-Diopside | > 1.5 wt.% Cr ₂ O ₃ = | HiCr-Diopside |
| Chromite | Cr ₂ O ₃ /Al ₂ O ₃ < 1.5 = | Cr-Spinel |
| Chromite | > 3 wt.% TiO ₂ = | Ti-Chromite |
| Rutile | > 15 wt.% FeOt _{tot} = | Fe-Rutile |
| Ilmenite | > 4 wt.% MgO = | Mg-Ilmenite |
| Ilmenite | > 53 wt.% FeOt _{tot} = | Ilmenite (altered) |
| Ilmenite | < 30 wt.% TiO ₂ = | FeTi-Oxide |
| Pyrope- | < 22 wt.% FeO & | diamond inclusion |
| Almandine- | 15wt.% < MgO < 5wt.% | (Group I) eclogitic |
| Grossular | & > 4 wt.% CaO | garnet |
| | & > 0.07 wt.% Na ₂ O = | |

Enlarged color prints and scanning electron microprobe (SEM) backscatter images of the grain mounts were used to aid mineral identification and to recognize possible inhomogeneities, intergrowths or exsolutions within individual grains. Grain colour was also used to confirm mineral identification. Minerals were identified and named using criteria similar to those of McClenaghan et al. (1996, 1998) and Ward et al. (1995) and are outlined above. A few grains could not be identified because their totals were too low. This was due to insufficient outcrop at the surface of the grain mount, inhomogeneity, strong alteration of the grains or compositions which contained elements not analyzed (e.g. Zr in zircon, S in sulfides). Grains that did not yield analyses with totals high enough to be unequivocally identified were labeled "unknown".

The target minerals in kimberlite exploration in the Kirkland Lake area are black Mg-ilmenite with ≥ 4 wt.% MgO (also called magnesian- or picro-ilmenites), purple Cr-pyrope in particular those with low CaO (subcalcic or harzburgite or dunite garnet), orange pyrope-almandine with high CaO and significant trace amounts of Na₂O and TiO₂ (diamond-inclusion eclogitic garnet), black (magnesio)-chromite with >62 wt.% Cr₂O₃ and >12 wt.% MgO, and emerald green Cr-diopside with high (≥ 1.0 wt.%) Cr₂O₃. Colour photos of these indicator minerals in C14 kimberlite and till samples are included in Averill and McClenaghan (1994) in Plates I and II.

Geochemical analysis

Prior to indicator mineral picking, the <1.0 mm non-ferromagnetic heavy mineral concentrates from glacial sediment and kimberlite samples were analyzed for 35 elements by Activation Laboratories Ltd., Ancaster, Ontario using instrumental neutron activation analysis (INAA) (Fig. 9). Samples were analyzed by this method because it allowed the entire sample to be analyzed without any destruction or loss of heavy minerals prior to indicator mineral

picking. Irradiated samples were stored for 6 months to allow radioactive elements to decay to safe levels prior to mineralogical studies. Concentrates were irradiated in 60 g vials. Samples weighing more than 60 g were split into multiple vials labeled A, B, C and each vial was then analyzed individually. Reported values for a multi-vial sample were then combined into one value using weighted averages (Appendix D). Lower detection limits for each element are listed in Table D.2. Analytical accuracy was monitored using previously irradiated Ontario Geological Survey (BRIM) reference standards (Appendix D) (Bloom, 1987; McClenaghan, 1990). Co results for the standards are not reported in Appendix D because of significant interference problems related to irradiating standards a second time. Analytical precision was monitored by comparing results for multiple vials with similar weights for an individual sample (Appendix D). Data for Ag, Cs, Hg, Ir, Mo, Ni, Se and Sn are not included in this report because the reported values are at or less than the lower detection limits listed in Table D.1.

The 500 g samples of glacial sediment and kimberlite were prepared at Bondar-Clegg and Company Ltd., Ottawa, Ontario, prior to geochemical analysis. Samples were oven dried at <40° C and sieved to <0.063 mm (-230 mesh). The <0.063 mm fraction was analyzed by Chemex Labs Ltd., Vancouver, B.C., for 32 elements using ICP-AES following a nitric-aqua regia digestion on a 1.0 g aliquot and for Au, Pt and Pd using fire assay-AFS on a 30 g aliquot. The fine fraction also was analyzed for Rb, Sr, and Zr using XRF on a 5 g pressed pellet, by X-Ray Assay Laboratories, Don Mills, Ontario. Analytical methods and lower detection limits for all methods are listed in Table E.2. Analytical accuracy was monitored by analyzing GSC reference standards. Analytical precision was monitored by comparing duplicate analyses of selected samples. Acceptable data are listed in Appendix E. Data for Ag, Bi, Cd, Ga, Hg, La, Mo, Pt, Pd, Tl, U and W are not included in this

report because the reported values are at or less than the lower detection limits listed in Table E.2.

Two samples of kimberlite from hole C14-05 and three samples from LAC Minerals diamond drill hole C14-M and C14-N were analyzed for whole rock and trace elements by X-Ray Assay Laboratories (XRAL), Don Mills, Ontario. LAC Minerals drill core was donated to D. Schulze at the University of Toronto, and subsequently sampled by B.A. Kjarsgaard. Samples were powdered in an agate mill prior to analysis. Analytical methods and detection limits are listed in Appendix F. Note that XRF-102 is XRF fused disc analysis for major elements with extended count times for the trace elements Rb, Nb, Zr; NA-BAS is instrumental neutron activation analysis; FeO was determined by titration; CO₂ by coulometry; and H₂O⁺ by the Penfield method. Split duplicates, as well as internal standards are not reported for brevity.

Archean bedrock sample 93MPB229 from hole C14-02 and sample 93MPB230 from hole C14-06 also were analyzed by XRAL. Major oxides, Rb, Sr, Y and Zr were analyzed using XRF on a fused disk prepared from a 2 g split. Au was analyzed by FA-DCP on a 30 g aliquot and As, Co, Ni, Cu and Zn were analyzed by ICP-ES on a 2 g aliquot following digestion in nitric and hydrochloric acids. Results are reported in Appendix F.

Gold grains

Gold grains were recovered from the sediment samples because of the proximity of the kimberlites to the Kirkland Lake gold camp and the high potential of the area for hosting additional gold deposits. Gold grains in glacial sediment samples were examined by Overburden Drilling Management Ltd. as part of the sample processing procedure (Fig. 9). Gold grains recovered from the <1.0 mm fraction during tabling and subsequent

panning were counted, their size estimated and then returned to the sample in preparation for geochemical analysis. Gold grains were classified using the three morphologic categories of DiLabio (1990) that reflect increasing distance of glacial transport: pristine, modified and reshaped (Appendix G). Pristine grains retain primary shapes and surface textures and appear not to have been damaged in glacial transport. Modified grains retain some primary surface textures but all edges and protrusions have been damaged during transport. Reshaped grains have undergone enough transport that all primary surface textures have been destroyed and the original grain shape is no longer discernible. The progression from pristine to reshaped grains is interpreted to represent increasing distance of glacial transport. Estimated gold assays for each sample were calculated by Overburden Drilling Management Ltd. based on the abundance and size of the gold grains recovered.

Textural and carbonate analysis

Textural and matrix carbonate analyses were completed at the GSC Sedimentology Lab. The grain size characteristics (% clay, silt and sand) of the <2.0 mm fraction of till were determined using dry sieving and pipette methods. The textural description of each sample listed in Appendix A.1 was determined using the % clay (<0.002 mm), % silt (0.002 to 0.063 mm), and % sand (0.063 to 2.0 mm). Matrix carbonate content of the <0.063 mm fraction was determined using the Chittick method of Dreimanis (1962).

Pebble lithology

The 5.6 mm to 6 cm (pebble) fraction was screened from the >2.0 mm (+10 mesh) fraction of sand, gravel and till samples (Fig. 9). Approximately 300 clasts were examined and classified into nine categories that reflect the major rocks types in the region: 1) felsic to intermediate intrusive rocks; 2) mafic intrusive rocks; 3) metavolcanic rocks; 4) ultramafic rocks; 5) metasedimentary rocks; 6) Paleozoic carbonate rocks from the Hudson Bay

Lowlands; 7) kimberlite, including Paleozoic carbonate xenoliths; 8) vein quartz; and 9) other or unknown rock types. Pebble lithology abundances are listed in Appendix H.

Paleozoic carbonate xenoliths eroded from kimberlite are distinguishable from carbonate clasts glacially transported from the Hudson Bay Lowlands. Paleozoic rocks from Hudson Bay Lowlands are small (<1 cm), light brown, well rounded, and many are striated. Paleozoic carbonate xenoliths from the kimberlite are up to 3 cm in size, very angular to subrounded, bluish grey to greenish grey to white and often have thermal alteration rims (e.g. Katsube et al., 1997) or fragments of kimberlite matrix still attached.

Biogeochemical sampling

In the summer of 1992, samples of black spruce bark and twig were collected from 9 sites along a 400 m north-south transect across the C14 kimberlite. Sample collection and preparation as well as analytical methods used for these tree tissue samples are described in detail by McClenaghan and Dunn (1995).

RESULTS

Kimberlite indicator mineral chemistry

Indicator mineral abundances for kimberlite and glacial sediment samples are summarized in Table 3. Only a portion of these grains were analyzed by electron microprobe to confirm and further classify their identity and results along with grain size and colour are reported in Appendix C.1 (on diskette). The most important mineral groups are discussed below.

Pyrope garnet

Mineral chemistry, size and colour for 695 pyrope grains from the C14 kimberlite and glacial sediments are listed in Appendix C.2. Table 3

* Sum of grains picked by Lakefield Research and grains picked by ODM (Averill and McClenaghan, 1994)

summarizes pyrope size and abundance in each sample as well as the abundance normalized to 10-kg sample weight. Pyropes are chemically characterized by high MgO levels (>13 wt.% MgO) and varying amounts of Cr₂O₃ up to 15 wt. %. MgO- (and Cr₂O₃-) rich pyrope garnets are exceedingly rare in upper crustal rocks. They are found mainly in alpine peridotites, mantle xenoliths carried to the surface by kimberlites or, more rarely, alkaline volcanic rocks with deep mantle sources (see compilation in Deer et al., 1982). Mantle-derived garnets found in kimberlite belong to three major petrogenetically and compositionally different groups: 1) Cr-poor titanian pyrope (≤ 4 wt.% Cr₂O₃), generally orange to deep red that belong to the Cr-poor megacryst suite which is genetically related to kimberlite; 2) purple (rarely green) Ti-poor, Mg- and Cr-rich pyrope from peridotitic xenoliths; and 3) orange pyrope-almandine-grossular garnets from eclogitic xenoliths. Only garnets of the two latter groups have been found as diamond inclusions; more specifically: purple subcalcic harzburgitic Cr-pyropes and orange Na-bearing pyrope-almandines from group I eclogites (Sobolev, 1977; Sobolev et al., 1973, 1993; Gurney, 1984, 1989; Gurney and Zweistra, 1995; McCandless and Gurney, 1989). These garnets are therefore important targets in diamond exploration. Only their chemical composition distinguishes them from other garnets with similar appearance.

Subcalcic harzburgitic garnets can be differentiated from other lherzolitic, harzburgitic, or dunitic garnets by plotting CaO versus Cr₂O₃, as shown in Figure 10. The striped area in Figure 11 shows the composition of lherzolitic garnets as defined by Sobolev et al. (1973; 1993). The diagonal dashed line separating lherzolitic and harzburgitic garnets is the 85% line defined by Gurney (1984). 85% of diamond inclusion garnets studied by Gurney fell below this line. These garnets are low-Ca, Cr-pyropes from harzburgitic or dunitic sources, which are also called subcalcic or G10 garnets after a classification by Dawson and Stephens (1975). The shaded area in the lower

A) C14 kimberlite

B) glacial sediments

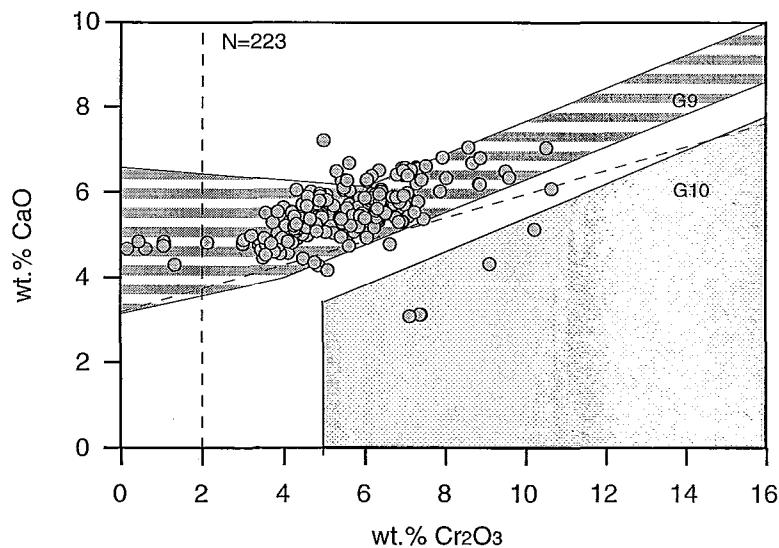

Figure 11. CaO versus Cr₂O₃ plot for garnets from: A) C14 kimberlite and B) glacial sediments. Striped area is the field for lherzolite garnets; shaded area is the composition of subcalcic garnets from the diamond stability field (Sobolev, 1977, 1993). Dashed diagonal line separates G9 and G10 garnets (Gurney, 1984). Dashed vertical line at 2 wt.% Cr₂O₃ is from Fipke et al. (1995).

right part of the plot shows the target field for subcalcic garnets defined by Sobolev (1971; 1977; 1993) and Sobolev et al. (1973; 1977; 1993) which is more restrictive than Gurney's 85% line (eliminating all garnets with $\text{Cr}_2\text{O}_3 < 5$ wt.%). Most garnets recovered from the two kimberlite samples from the C14 pipe plot within the lherzolite field of Sobolev. Only five garnets from till sample 93MPB023 sitting directly on kimberlite in hole C14-05, and two garnets from the kimberlite sample 93MPB204 plot within Sobolev's subcalcic field (Fig. 11), suggesting a low diamond potential for the C14 kimberlite. Garnets in glacial sediments around the C14 pipe display a similar range of compositions as the C14 kimberlite.

The vertical dashed line at 2 wt. % Cr_2O_3 in Figures 10 and 11 separates Cr-poor eclogitic, pyroxenitic and crustal garnets from peridotitic Cr-pyropes (Gurney, 1984; Schulze, 1995; Fipke et al., 1995). Most megacryst garnets also plot left of the 2 % line although some may contain up to 4 wt. % Cr_2O_3 (Fipke et al., 1995; Schulze, in press). Only 33 out of 695 garnets plot left of the 2% Cr_2O_3 line and most of them (24) have high levels of TiO_2 (> 0.5 wt.%) characteristic of Cr-poor megacryst garnets. A few Mg-rich almandines and Fe-rich pyropes (Appendix C.2) approach compositions of eclogitic garnets, but none of them have the essential low FeO_{tot} levels (< 22 wt.%; Fipke et al., 1995; Schulze, in press) that are characteristic of eclogitic garnets.

Almandine-Spessartine-Grossular garnet

The majority of orange to red garnets analyzed here are characterized by high FeO and/or MnO contents with additional CaO and MgO . These garnets belong to the almandine-spessartine-grossular solid-solution series and are found mainly in metapelites and metabasites (garnet-schists and amphibolites) (Deer et al., 1982) which are of local derivation from Archean lithologies. Although optically very similar to eclogitic garnets, they are of no interest in kimberlite exploration.

Andradite and Cr-andradite garnet

Numerous pale green to yellow-green andradites were recovered from most glacial sediment samples from the C14 property (Appendix C.3) but not from the kimberlite samples 204 and 205 or the immediately overlying till sample (023). They were picked because of their similarity to Cr-diopside. On closer examination, they can be distinguished from Cr-diopside by their more frosted appearance, yellowish-greenish color and by their isotropic optical character. Cr-diopside, in contrast, is emerald green to pale green or colorless without yellowish tinge, usually transparent, has well developed cleavage and is optically anisotropic. The green andradites are unusual in their composition in that they contain varying amounts of Cr_2O_3 up to > 9 wt.% but little TiO_2 and Al_2O_3 (<2 wt.% each), i.e. they are essentially solid solutions of andradite ($\text{Ca}_3\text{Fe}_2(\text{SiO}_4)_3$) and uvarovite ($\text{Ca}_3\text{Cr}_2(\text{SiO}_4)_3$). Some andradite contain variable amounts of MgO with concomitantly decreasing CaO and Fe_2O_3 and increasing SiO_2 indicating intergrowths with, or gradation to, serpentine.

Cr-Diopside

Diopside mineral chemistry, size and colour for individual grains is reported in Appendix C.4. Diopside size and abundance and normalized abundance is reported in Table 2. Green Cr-diopside is an important kimberlite indicator mineral, originating from mantle xenoliths (lherzolites, pyroxenites and eclogites) and intergrowths with ilmenite (Cr-poor megacryst suite). Kimberlites contain diopsides with a wide range of Cr_2O_3 content (up to 6 wt.%; Stephens and Dawson, 1977). Diopside from other ultrabasic rocks (see Table 52 of Deer et al. 1978) may contain up to approximately 1.5 wt.% Cr_2O_3 .

Clinopyroxene, including Cr-diopside, occurs in a variety of rocks in the Kirkland Lake region (Table 6 of Fortescue et al., 1984). Discrimination

between kimberlitic and other diopsides on the basis of Cr_2O_3 content therefore is important. It may be difficult, but diopsides with ≥ 1.5 wt.% Cr_2O_3 are most likely from kimberlites. Diopsides recovered from the C14 area were divided into two groups based on their Cr_2O_3 content: 1) Cr-diopside (0.5 to 1.5 wt.% Cr_2O_3); and 2) HiCr-diopside (≥ 1.5 wt.% Cr_2O_3). Diopsides recovered from the C14 kimberlite contained between 1.02 and 4.15 wt.% Cr_2O_3 , 77% of them were HiCr-diopsides. Glacial sediments contain a similar proportion of HiCr-diopsides, 70 % of diopsides in the till and sand&gravel samples contained >1.5 wt.% Cr_2O_3 .

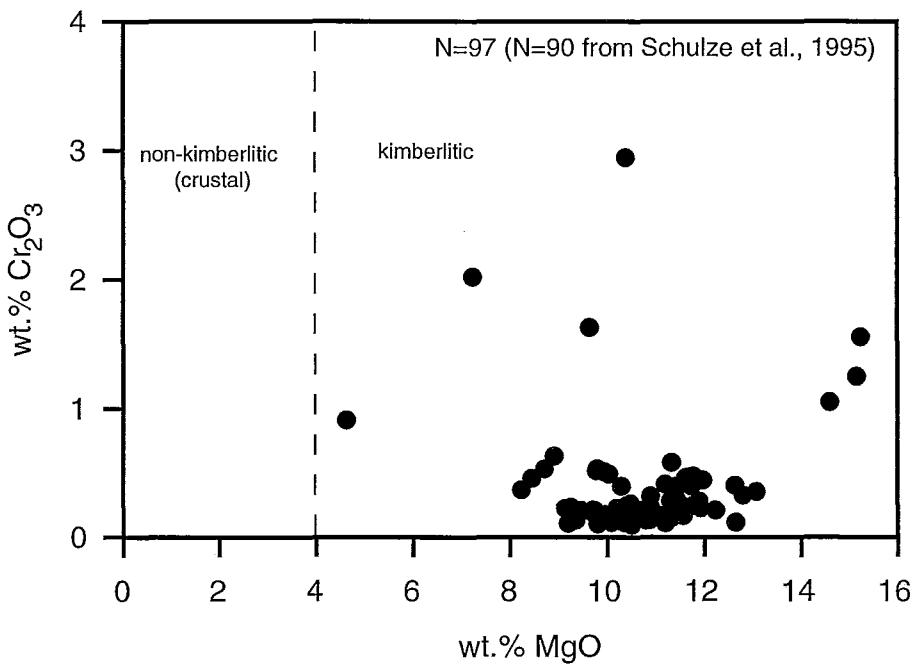

Mg-ilmenite

Chemistry, size and colour for individual ilmenite grains are reported in Appendix C.5. Table 3 summarizes the number and size of Mg-ilmenites and normalized abundances in each sample. Ilmenites from kimberlite contain >4 wt.% MgO and are referred to as Mg-ilmenite (Mitchell, 1973; Haggerty, 1975). Ilmenites in glacial sediments around the C14 kimberlite have two distinct compositions, (1) Mg-ilmenites with >4 wt.% MgO that mimic the composition of ilmenites in the kimberlite and (2) ilmenites with <4 wt.% MgO and very little Cr_2O_3 interpreted to be derived from regional bedrock sources such as mafic volcanics, mafic to intermediate intrusives and Temiskaming sediments (Table 6 in Fortescue et al., 1984.). Because only six Mg-ilmenite grains were recovered from the C14 kimberlite, their compositional data were combined with published C14 Mg-ilmenite data from Schulze et al. (1995) and plotted in Figure 12. Mg-ilmenites from the C14 kimberlite form a "U"- shaped curve with most grains clustering at the bottom of the U, containing between 6 and 12 wt.% MgO and <1 wt.% Cr_2O_3 .

Hematite , Leucoxene and Rutile

A few hematite, leucoxene and rutile grains that were analyzed are accessory minerals or alteration products of ilmenite or perovskite. Leucoxene is a

A) C14 kimberlite

B) glacial sediments

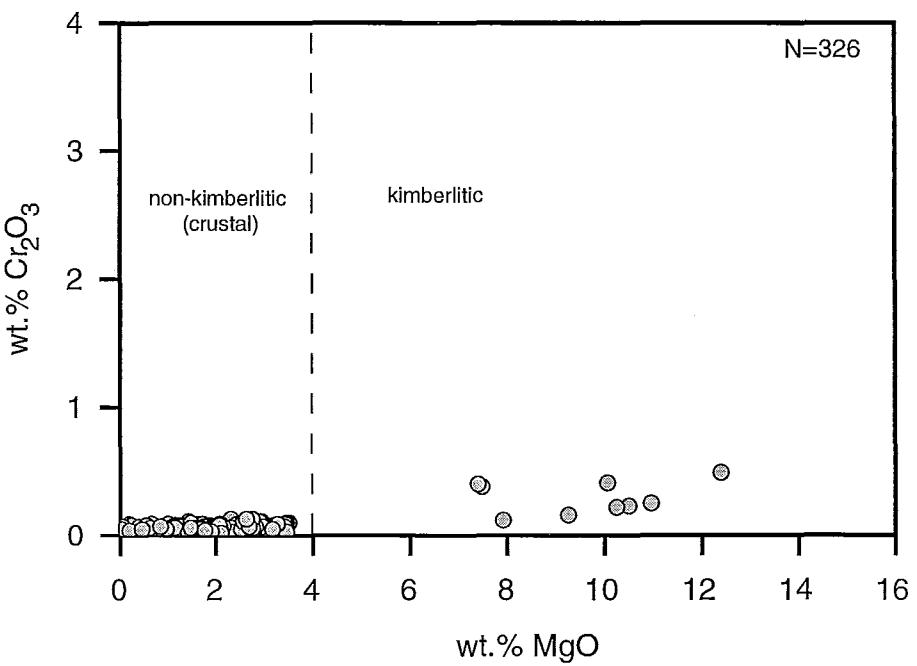

Figure 12. Cr₂O₃ versus MgO plot for ilmenite grains from:
A) C14 kimberlite and B) glacial sediments.

mixture of Fe- and Ti-rich phases (rutile, titanite and hematite). In this study the name leucoxene is used for all non-stoichiometric mixtures of SiO_2 , FeO and TiO_2 with minor Al_2O_3 and CaO .

Chromite and Cr-spinel

Size, colour and mineral chemistry for individual chromite grains are reported in Appendix C.6. Chromite abundance and size distribution for each sample is summarized in Table 3. The analyzed chromites have a wide range of Cr_2O_3 contents, ranging from Cr-spinels with <25 wt.% Cr_2O_3 to chromites with up to 65 wt.% Cr_2O_3 . Chromite occurs in a variety of basic and ultrabasic rocks in the region including kimberlite (e.g. Table 6 in Fortescue et al., 1984). Similar to Cr-diopsides, the Cr_2O_3 contents of kimberlitic and non-kimberlitic chromites overlap. Very chromium and magnesium rich (>62.5 wt.% Cr_2O_3 , 12-17 wt.% MgO , < 1 wt.% TiO_2) (magnesio-) chromites in kimberlite have been found as inclusions in diamonds (Fipke et al., 1989; Gurney and Moore, 1993). The Cr_2O_3 versus MgO plots for chromites from the C14 pipe (Fig. 13a) show that two grains contain sufficient MgO and Cr_2O_3 to plot in the diamond inclusion field defined by Fipke et al. (1989). Schulze (1996c), however, argues that chromites coexisting with diamond do not have to fall into this field due to possible subsequent re-equilibration in the open system of the upper mantle. Chromites in the glacial sediments (Fig. 13b) show a similar range of MgO versus Cr_2O_3 compositions to the kimberlite.

Other minerals

Some garnet grains exhibited kelyphitic rims or overgrowths which were analyzed, in some cases, because no fresh garnet was exposed on the grain surface. Kelyphite is a mixture of ortho- and clinopyroxene, phlogopite, Al-rich spinel and serpentine; some kelyphite rims were almost pure phlogopite. Other minerals analyzed in this study were picked because they resembled kimberlite indicator minerals. Black amphibole and tourmaline were picked

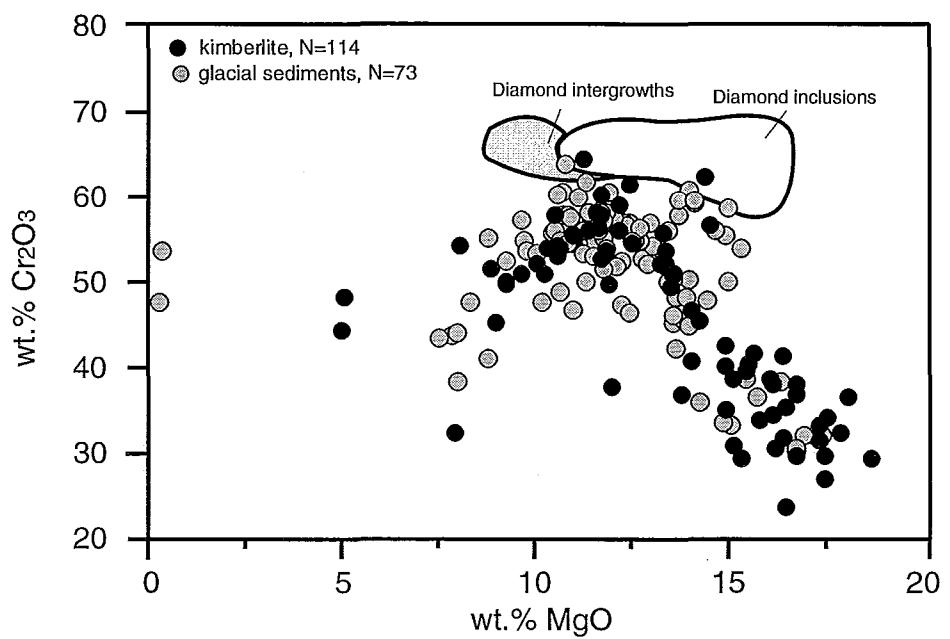

Figure 13. Cr_2O_3 versus MgO plot for chromite grains from the C14 kimberlite and glacial sediments.

because they look similar to Mg-ilmenite or chromite. Pale green serpentine was picked because it resembled Cr-diopside. Perovskite, a dark brown to black oxide, is a common groundmass phase in kimberlites and has been found in the C14 kimberlite (Armstrong et al., 1997), however, it is not used as an indicator mineral. Perovskite, a dark brown to black oxide, is an accessory mineral in kimberlites, however, it is not used as an indicator mineral because it also occurs in many other undersaturated alkaline rocks. .

Kimberlite geochemistry

Whole rock major and trace element chemistry for five kimberlite samples from various depths within the C14 kimberlite are listed in Appendix F. Two core samples are from drilling performed in the present study; the other three samples are from LAC Minerals drill core donated to D. Schulze at the University of Toronto, and subsequently sampled by B.A. Kjarsgaard. The five C14 kimberlite samples are all broadly similar in their major and trace element concentrations. Furthermore, when compared to archetypal (Gp I) kimberlites from various global localities, the C14 samples plot between the world 'high' values and the world 'low' values, at concentrations slightly lower than the global 'world average' (Fig. 14a and b). In other words, the C14 kimberlite samples are quite typical in terms of their geochemical signature as compared to archetypal (Gp I) kimberlites worldwide, i.e. high concentrations of compatible elements of the first series of transition elements (Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Co; but specifically Ni and Cr), as well as high concentrations of a variety of incompatible elements such as the rare earth elements (REE; especially the light REE) and also Rb, Ba, Sr, Nb, Zr, Hf, Ta, U, Th, Pb.

Till geochemistry

Major and trace element data for the heavy mineral and fine fractions of glacial sediments are listed in Appendixes D and E. The <1.0 mm non-

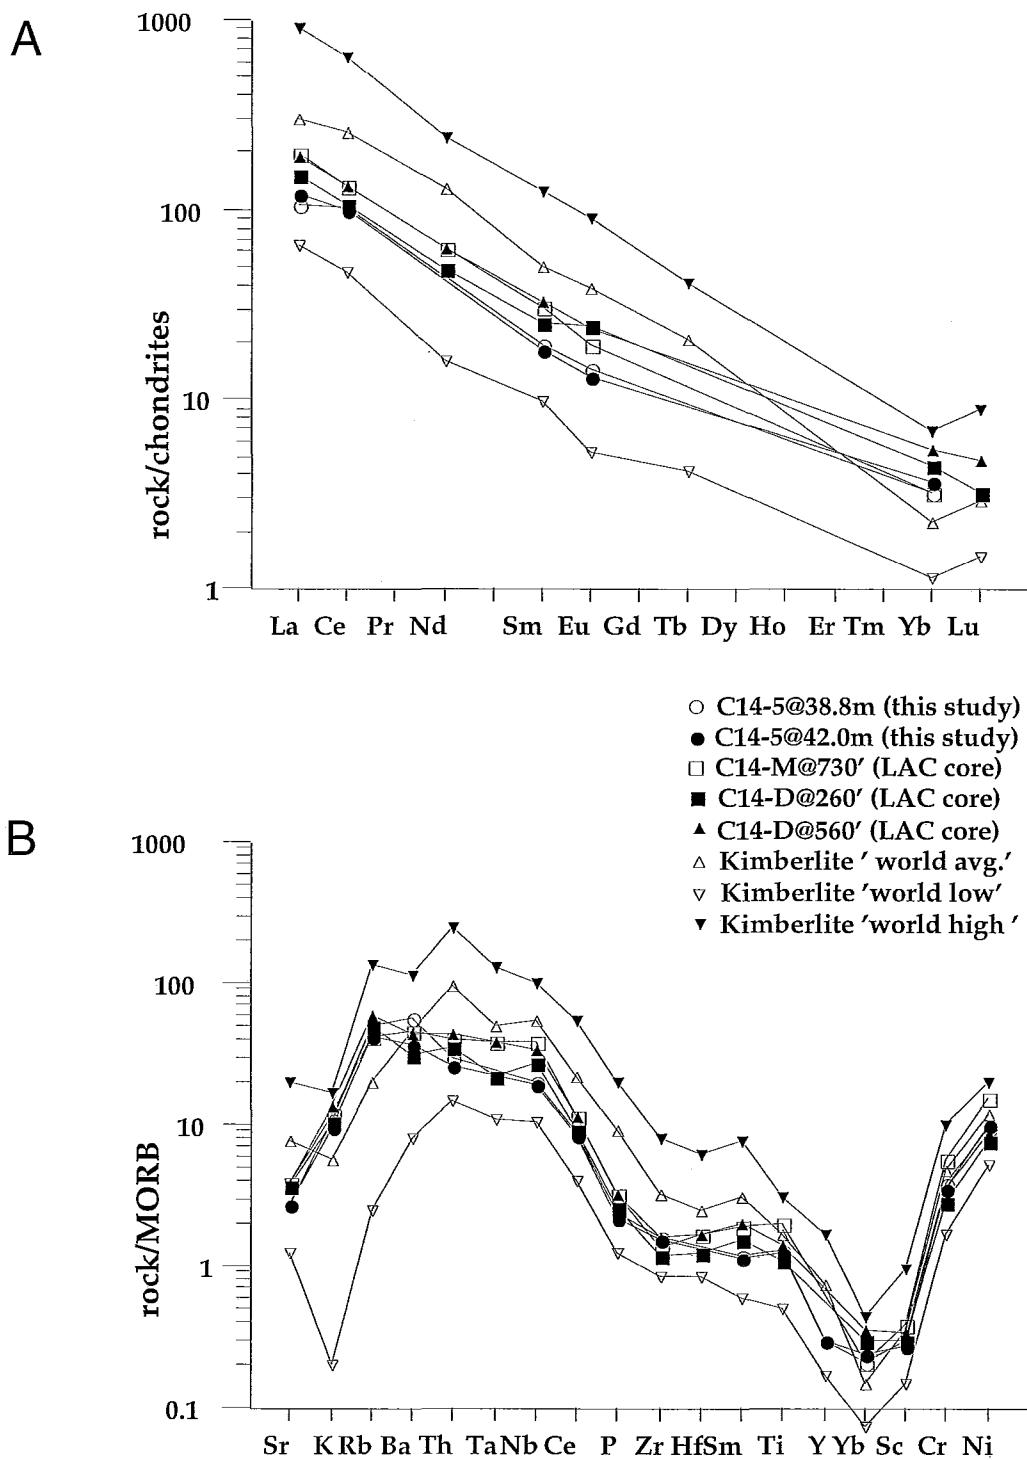

Figure 14. A.) REE plot for two diatreme facies C14 kimberlite samples analysed this study, plus three other C14 samples from LAC drill core. Chondrite normalization values from Nakamura (1974). B.) Pearce plot (samples normalized to MORB) for the five C14 samples. For comparison in figures A and B, world average plus high and low values for archetypal (Gp I) kimberlite are also shown.

ferromagnetic heavy mineral fraction of C14 kimberlite is characterized by high concentrations of Cr, Ta, La, Ce, Nd, Sm and Eu and the <0.063 mm fraction contains high concentrations of Ba, Ca, Co, Cr, K, Mg, Mn, Ni, Sr and Ti. Till sample 93MPB023 sitting directly on kimberlite in hole C14-05 (Fig. 15) has elevated concentrations of Au, Cr, Sr, Ta, La, Ce, and Eu in the heavy mineral fraction and Ba, Co, Cr, Tot Fe, K, Mg, Ni, Sr and Ti in the <0.063 mm fraction which reflect incorporation of the underlying kimberlite bedrock. Fine-grained glaciolacustrine sediments (silt and clay) overlying the till in hole C14-05 display a decreasing abundance of most elements with increasing depth (Fig. 15). This trend may be related to the increasing silt content with depth (see Appendix A.1, grain size analysis for silt samples 93MPB207 to 216).

Gold grains and geochemistry

The number, size and shape of visible gold grains recovered from glacial sediment and kimberlite are reported in Appendix G. Because of the variable weight of the bulk samples (4 to 25 kg), gold grain counts were normalized to 10 kg of <2 mm (-10 mesh) material. Normalized values are reported in Appendix G and these values are discussed below. Till samples contain between zero and 29 visible gold grains, although most samples contain between 5 and 15 gold grains. Over 90% of the gold grains recovered from the glacial sediments are reshaped (well traveled) grains that are <100 µm in size and are considered to be background grains. Although visible gold grains have been recovered from kimberlitic rocks in the Kirkland Lake area (McClenaghan et al., 1995; McClenaghan et al. 1996), none were found in C14 kimberlite samples 93MPB204 and 205. Till sample 93MPB011 resting on bedrock in hole C14-03 is very anomalous, containing 29 visible gold grains and assaying 51,300 ppb Au. Till sample 93MPB023 resting on kimberlite bedrock contained no visible gold grains yet assayed a moderately anomalous 3020 ppb Au.

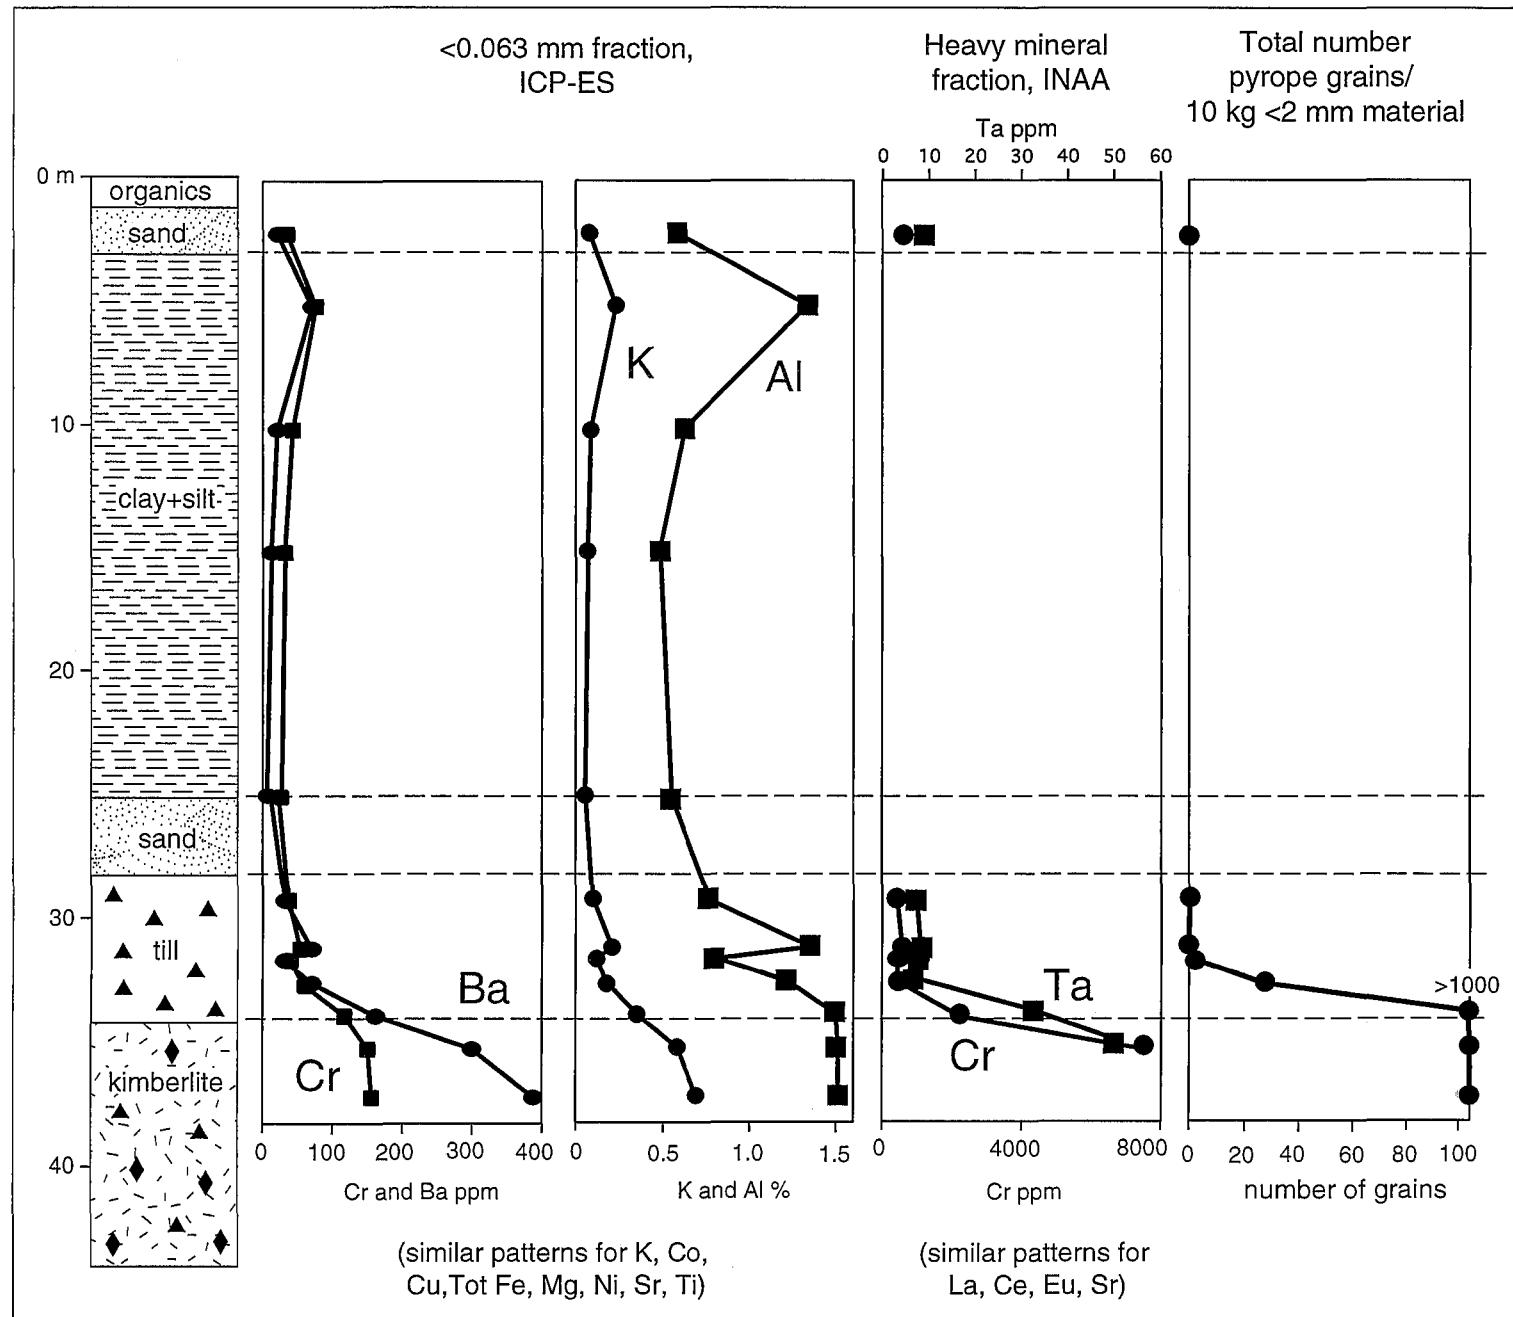

Figure 15. Geochemistry and pyrope abundance in glacial sediments and kimberlite in GSC drill hole C14-05 overlying the C14 kimberlite..

Pebble lithology

The number percent of pebbles (5.6 mm to 6 cm) in nine lithologic categories are listed in Appendix H. The pebble fraction of till around the C14 pipe is dominated by metavolcanic rocks. A few kimberlite pebbles were found in till samples 93MPB009 and 010 in hole C14-02, just west of the kimberlite. Approximately 30% of the pebble fraction in till sample 93MPB023 sitting directly on kimberlite, is composed of kimberlite fragments.

Biogeochemical studies

Geochemical data for black spruce twigs and bark collected along a 400 m north south transect over the C14 kimberlite are reported in McClenaghan and Dunn (1995). Sr, Rb, Ba (Fig. 16), Cr, Na, Cd, Co, Cs, Zn and REE concentrations in black spruce twigs and Sr, Ba and Zn concentrations in black spruce bark are elevated overlying the C14 kimberlite. These patterns overlying the kimberlite indicate the biogeochemical studies may help in delineating kimberlitic bodies (McClennaghan and Dunn, 1995; Dunn and McClennaghan, 1996).

DISCUSSION AND CONCLUSIONS

Cr-pyrope from the C14 kimberlite is overwhelmingly from disaggregated lherzolitic xenoliths. Only a few subcalcic garnets from harzburgite or dunite were observed. A small population of Ti-rich, Cr-poor garnets probably are megacrysts. No eclogitic garnets were found. These findings are in accordance with studies by Schulze (1993a), Meyer et al. (1994), Sage (1996) and Vicker (1997) who found similar garnet compositions and proportions of source rocks for the C14 pipe. Brummer et al. (1992) have reported eclogitic xenoliths from this kimberlite, but mineral chemistry data are not reported.

The high Cr₂O₃ levels of diopside in glacial sediments (70 % containing >1.5 wt.% Cr₂O₃) suggests that they are mainly derived from the C14 kimberlite, of

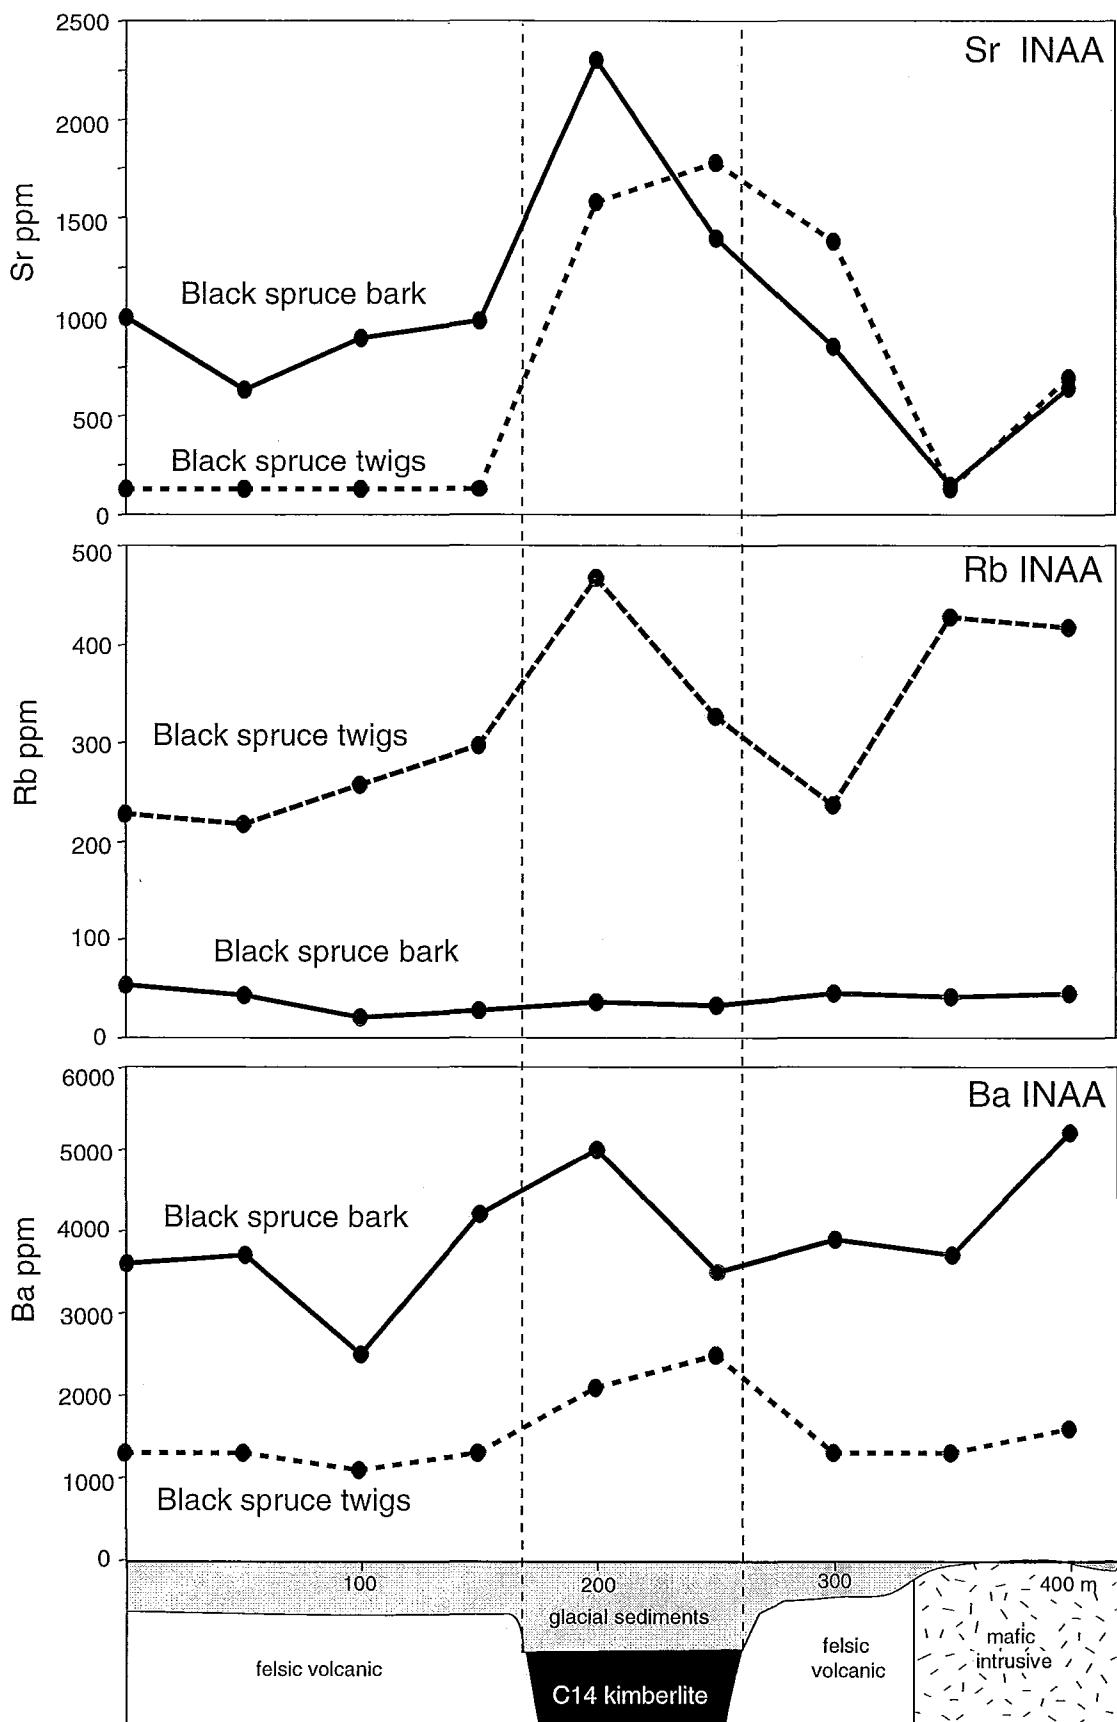

Figure 16. Distribution of Sr, Rb and Ba, determined by INAA analysis, in the ash of black spruce bark and twigs along a north-south transect across the C14 kimberlite (from Dunn and McClenaghan, 1996)

which 100% of the diopsides analyzed contain >1.0 wt.% Cr₂O₃. Cr-diopsides in garnet lherzolites from the C14 pipe have Cr₂O₃ ranging from 0.8 to 2.5 wt. % (Meyer et al., 1994). It is assumed that Cr-diopsides with higher Cr₂O₃ analyzed here are also mantle derived peridotites since diopside from Cr-poor megacrysts or eclogites have considerably lower Cr₂O₃ levels (Eggler et al., 1979; Shee and Gurney, 1979).

The compositional range of chromite grains from this study is typical of chromite macrocrysts from kimberlites in general and in accordance with other studies of C14 spinels (Armstrong et al., 1997; Meyer et al., 1994). Two (magnesio-) chromites out of a total of 187 in this study contain sufficient MgO and Cr₂O₃ to plot in the diamond inclusion field, consistent with the low number of subcalcic garnets found in the C14 kimberlite. Brummer et al. (1992b) mention finding several magnesiochromites in C14 kimberlite samples that also yielded diamonds. Sage (1996) found no diamond inclusion field chromites among 47 chromites analyzed from the C14 pipe. Glacial sediments display a similar range of chromite compositions as the kimberlite samples, indicating most are derived from the C14 kimberlite.

Mg-ilmenites are the least abundant indicator mineral in the C14 pipe. The few grains that were recovered in this study and by Schulze et al. (1995) contain between 8 and 14 wt.% MgO and <1 wt. % Cr₂O₃. Sage (1996) reported a similar compositional range, from 8.8 and 14.3 wt. % MgO.

In summary, the kimberlite indicator minerals of the C14 pipe are dominated by Cr-pyrope and chromite (\pm Cr-diopside) derived from lherzolitic xenoliths with only a minor proportion from harzburgite and dunite sources. No evidence of eclogitic xenoliths could be found in this study. The low numbers of Cr-poor pyrope, diopside and Mg-ilmenite point to a low contribution from the Cr-poor megacryst suite which can be dominant in other kimberlites in

the Kirkland Lake kimberlite field (Schulze, in press). The presence of subcalcic garnet and Cr-rich and (magnesio-) chromite suggests a moderate diamond potential for the C14 pipe. This is consistent with the recovery of 8 macrodiamonds in a 15.04 ton kimberlite sample from the C14 pipe by LAC Minerals (reported in Brummer et al. 1992b).

The range in glacial sediment sample weights is large, 4 to 25 kg. Therefore indicator mineral counts were normalized to a 10-kg weight of <2 mm (table feed) material for comparison between samples (Table 2). The relative abundance of indicator minerals in the C14 kimberlite, listed in decreasing order of abundance, is: pyrope > Cr-diopside > chromite > Mg-ilmenite. These relative abundances are mimicked in till overlying (hole C14-05) and just down-ice (hole C14-02) of the kimberlite. Indicator mineral chemistry for grains recovered from the glacial sediments around the C14 kimberlite are also similar to that for the kimberlite.

Kimberlite samples from the C14 pipe contain tens of thousands of indicator mineral grains in 10-kg. Unfortunately, hole C14-01 which was drilled north of the pipe to test background indicator mineral concentrations, did not intersect till. Instead, background concentrations for the C14 area were estimated from the upper, more distally derived parts of thick till sequences in the other drill holes: 0 to 3 pyrope, 0 to 2 Cr-diopside, 0 chromite and 0 Mg-ilmenite. KLIP holes northwest and northeast of the C14 kimberlite do not contain kimberlite indicator minerals (Fortescue et al., 1984) supporting the observation from the GSC holes that background concentrations of indicator minerals are very low to none.

Lower till samples collected from directly over the C14 pipe in Hole C14-05 (Fig. 14) and just down-ice, in hole C14-02, contain anomalous concentrations of indicator minerals (tens to thousands of grains), contain elevated Cr, Sr, Ta,

La, Ce, and Eu in the heavy mineral fraction and Ba, Co, Cr, Tot Fe, K, Mg, Ni, Sr and Ti in the <0.063 mm fraction, and contain several kimberlite clasts in the pebble (+10 mesh) fraction. Upper till samples in these two holes and till samples from holes C14-03 and C14-04 contain background concentrations of indicator minerals, no kimberlite clasts and no geochemically anomalous abundances. Till in hole C14-08, 2 km southwest of the kimberlite, contains slightly anomalous concentrations of indicator minerals, 14 pyrope, 6 Cr-diopside and 2 chromite. However, till geochemical abundances in these till samples do reflect kimberlite.

Most glacial sediment samples from the C14 property contain andradite, including the one sand sample from hole C14-01 drilled north of the kimberlite (Appendix C.3). Till sample 93MPB049 from the upper part of till in hole C14-08 contains the most andradite, 15 grains in 25 kg of till. In contrast, till samples that contain kimberlite clasts and anomalous concentrations of kimberlite indicator minerals (93MPB023, 93MPB009 and 010) are devoid of andradite. Andradite is found occasionally in kimberlites (Mitchell, 1986) but its source in the till in southern Clifford Township is unlikely to be the C14 kimberlite as none were found in the two C14 kimberlite samples. Cr-Andradites of very similar composition and paragenesis to the grains analyzed here have been reported from Reaume Township, 80 km northwest by Duke and Bonardi (1982), where they occur in serpentinized veins in wehrlites as a product of the breakdown of olivine, diopside and Cr-spinel. Andradites in glacial sediments may also be eroded from zones of alkalic metasomatism north of, and associated with, the Destor-Porcupine deformation zone (R. Sage, pers comm, 1998). Averill and McClenaghan (1993) also suggested that andradite in glacial sediments around the C14 and the Diamond Lake pipes was eroded from shear zones. The absence of Cr-andradites in the C14 kimberlite samples and their presence in other glacial sediment samples from the Kirkland Lake area (e.g. Fortescue et

al., 1984; Averill and McClenaghan, 1993; McClenaghan et. al., 1996) indicates that the Cr-andradites reported here are not related to kimberlite.

FUTURE WORK

Results from similar studies around the A4 pipe are in preparation. Olivine from kimberlite is being examined to determine its usefulness as indicator minerals. Additional ilmenites in kimberlite boulders collected from gravel pits in the Munro and Misema River eskers are being analyzed to document kimberlite dispersal in eskers and to determine the boulders' kimberlitic sources. Results for till and kimberlite samples collected from the Peddie kimberlite pipe and adjacent area, near New Liskeard, Ontario, in the fall of 1997 will be released at a later date.

ACKNOWLEDGMENTS

The study was funded by the Geological Survey of Canada, under the Minerals Program of the Canada-Ontario Northern Ontario Development Agreement (NODA) between 1991 and 1995. Regal Goldfields Ltd. is thanked for providing access to the C14 property. J.J. Brummer, D.J. Schulze, and T. Obradovitch are thanked for sharing their time, samples and geological information about the C14 kimberlite. The staff of the Ontario Ministry of Northern Development and Mines Drill Core Library, Swastika, are thanked for providing logistical support and unlimited access to their facility. Excellent service was provided by JR Drilling Ltd., Heath and Sherwood Drilling Inc., Overburden Drilling Management Ltd., Bondar-Clegg and Co. Ltd., Chemex Ltd., X-Ray Assay Laboratories Ltd., and the Bon Air Motel and Tim Hortons Donut shop in Kirkland Lake. R.N.W. DiLabio and C.A. West provided able assistance in the field and R.C. Paulen completed the pebble counts. L.H. Thorleifson reviewed the manuscript.

_____ top of sample interval
93MPB002 sample number
_____ bottom of sample interval

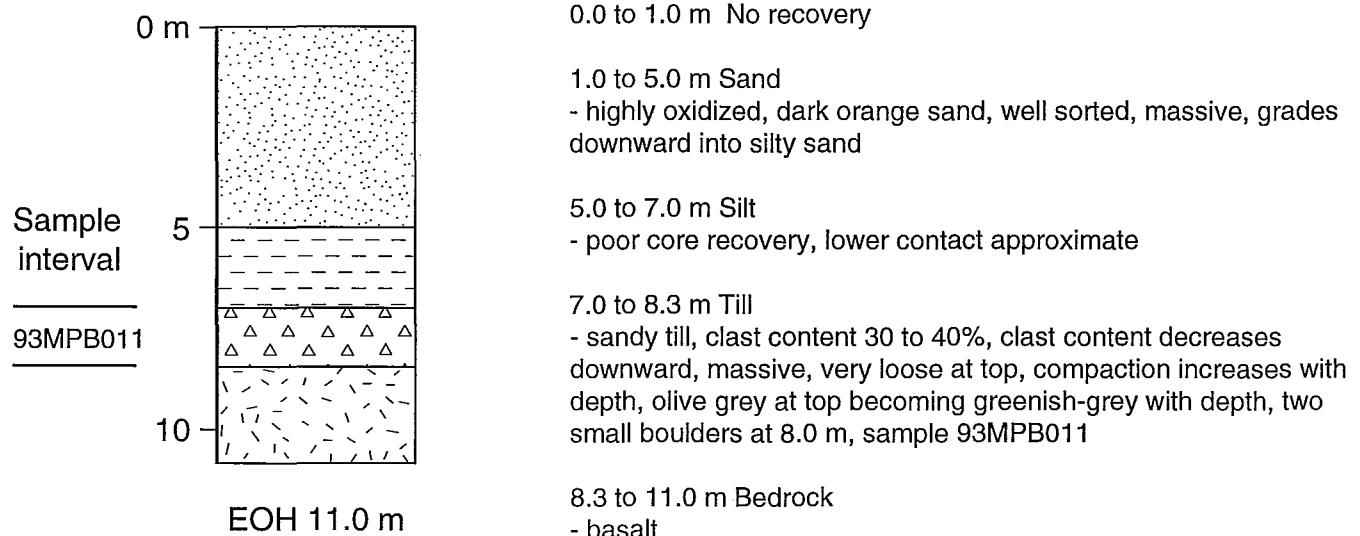

- 93MPB217 spot sample for geochemistry/mineralogy

Hole C14-01

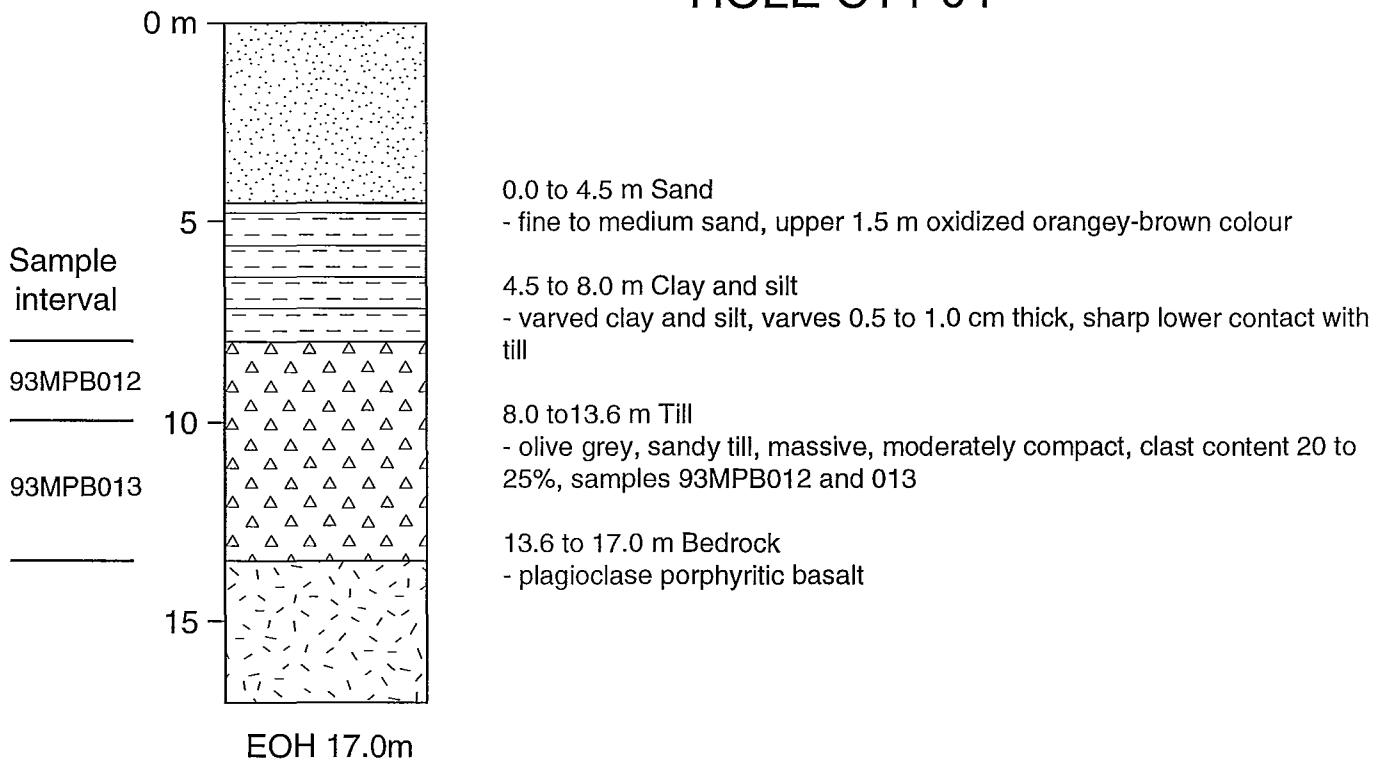

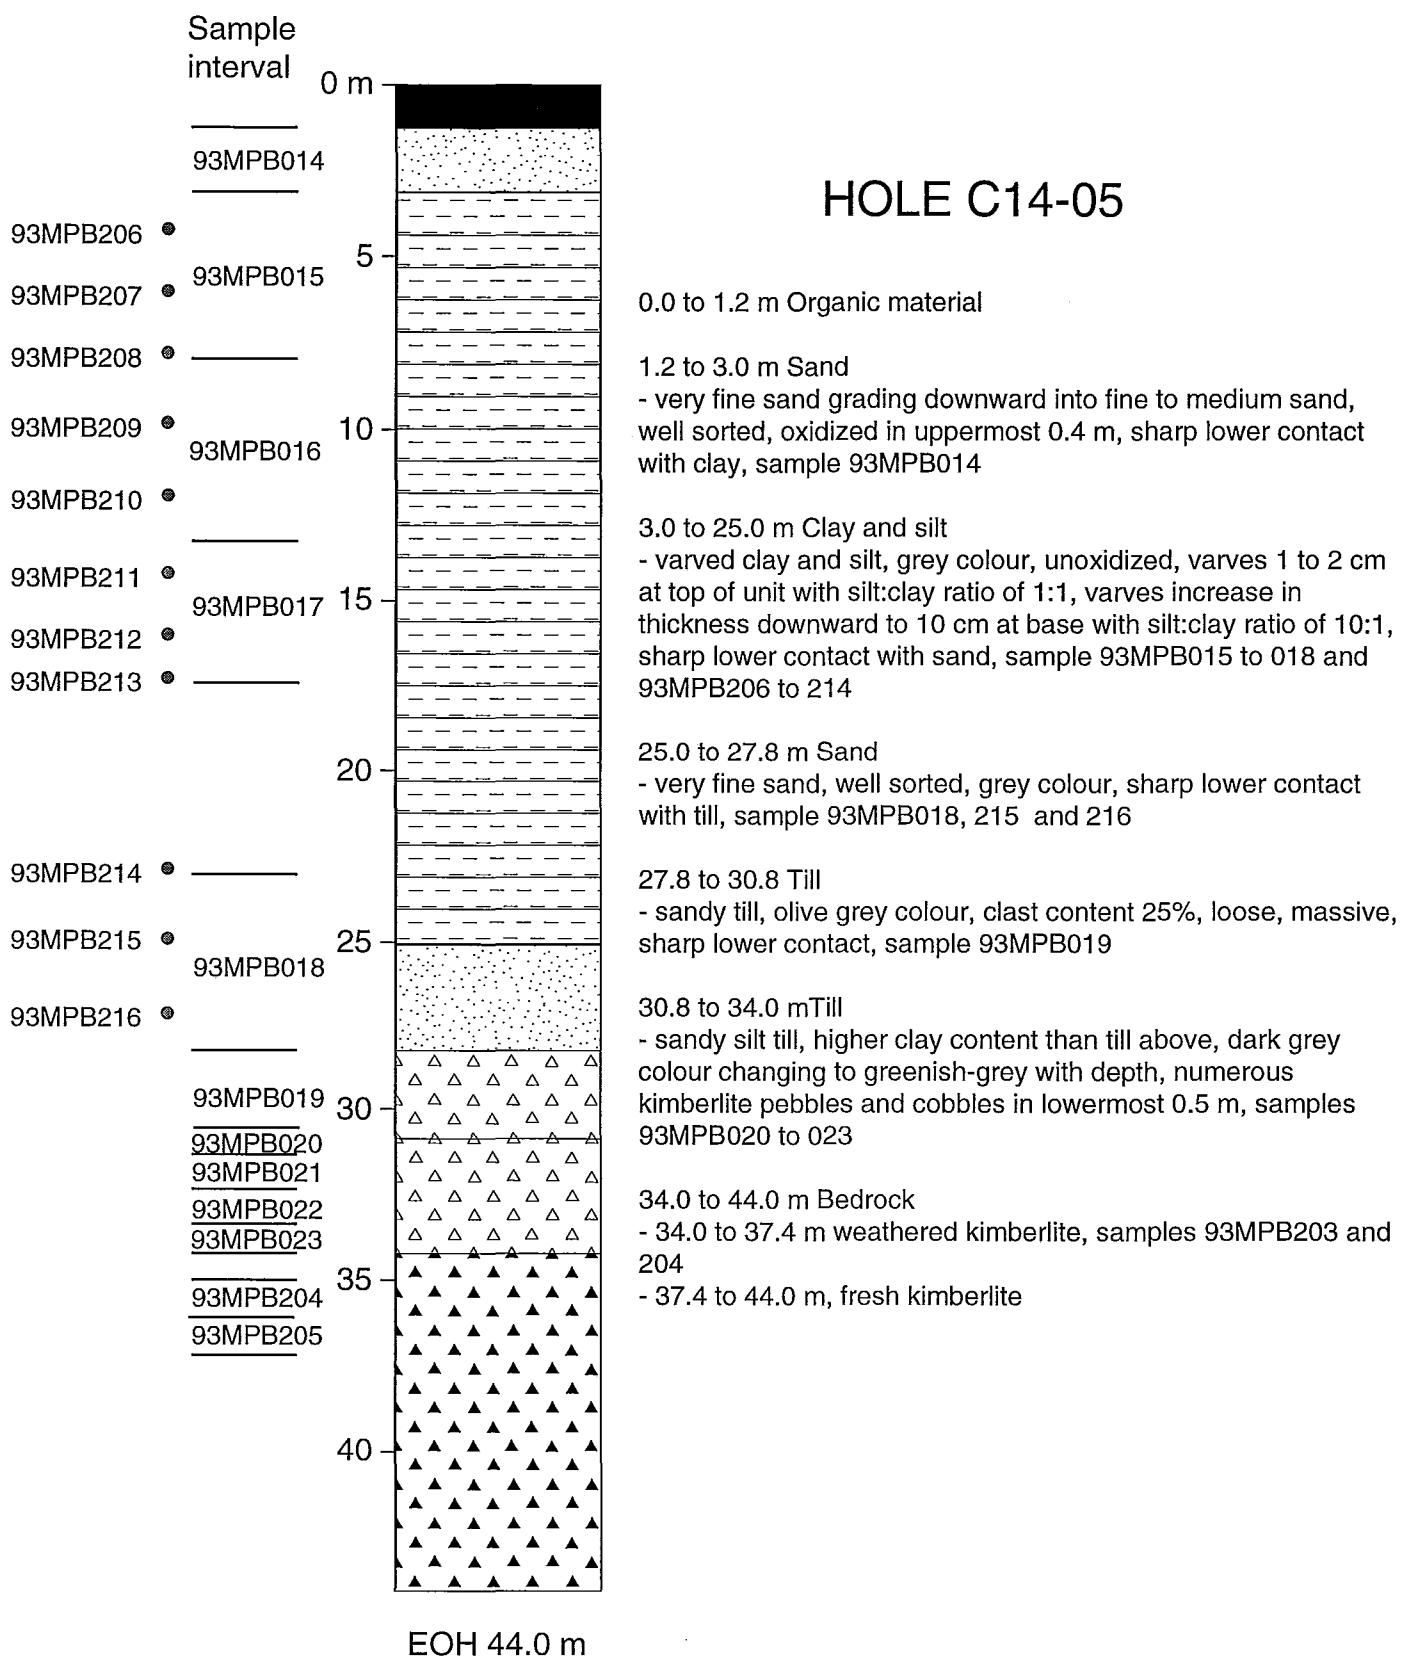

HOLE C14-03

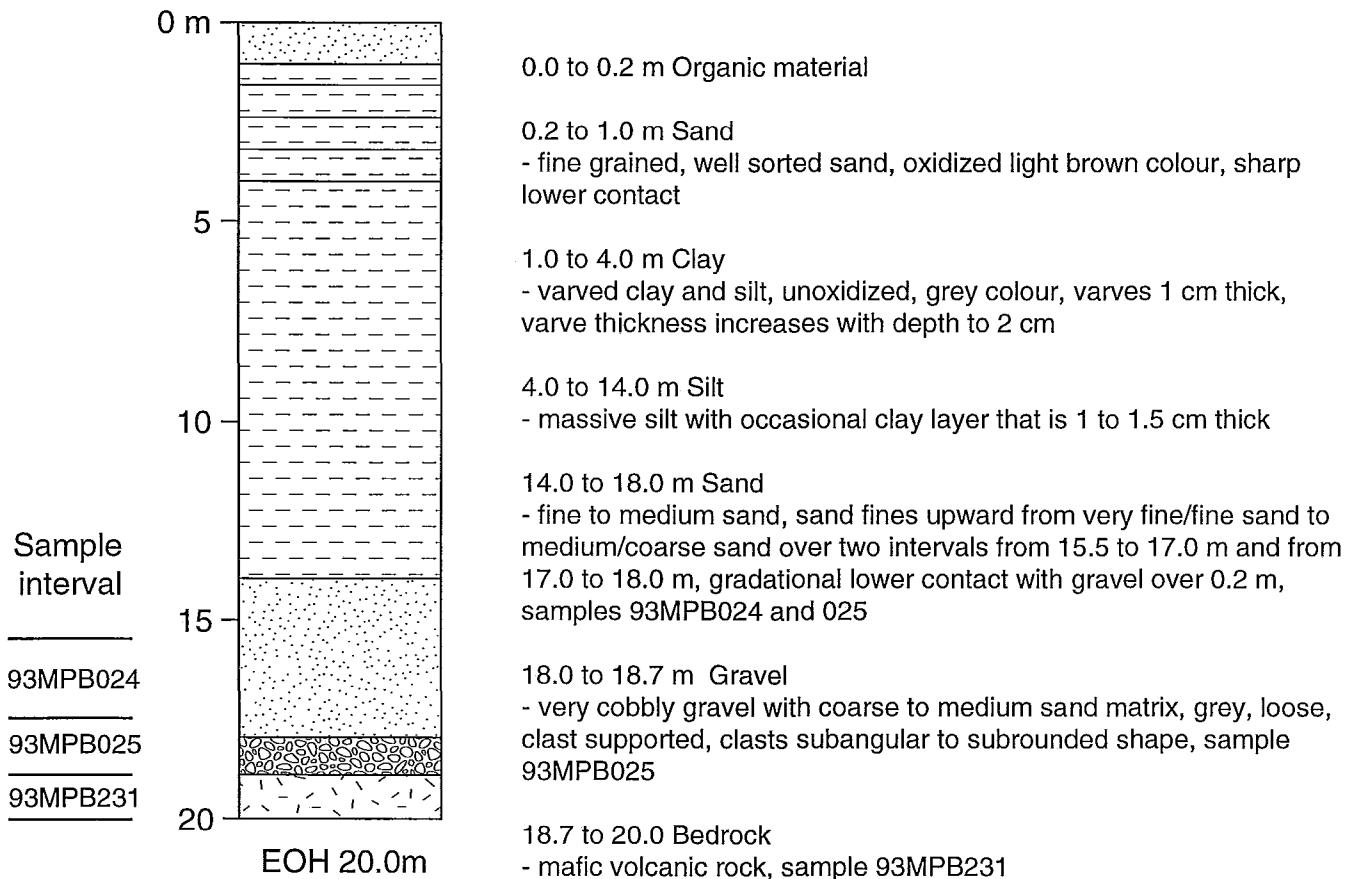

HOLE C14-04

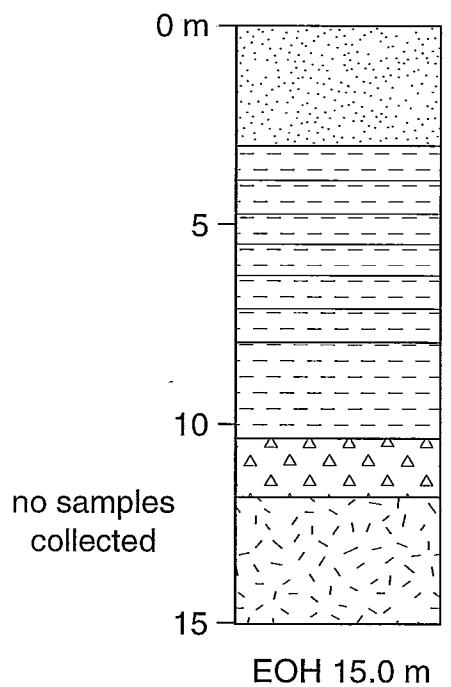

HOLE C14-06

HOLE C14-07

0.0 to 3.0 m Sand

- very fine sand, highly oxidized orangey-brown, grades down into fine to medium sand, sharp lower contact

3.0 to 8.0 m Clay and silt

- varved clay and silt, varves 0.5 to 1.0 cm thick

8.0 to 10.4 m Silt

- grey silt, massive, occasional 1 cm thick layer of dark grey clay

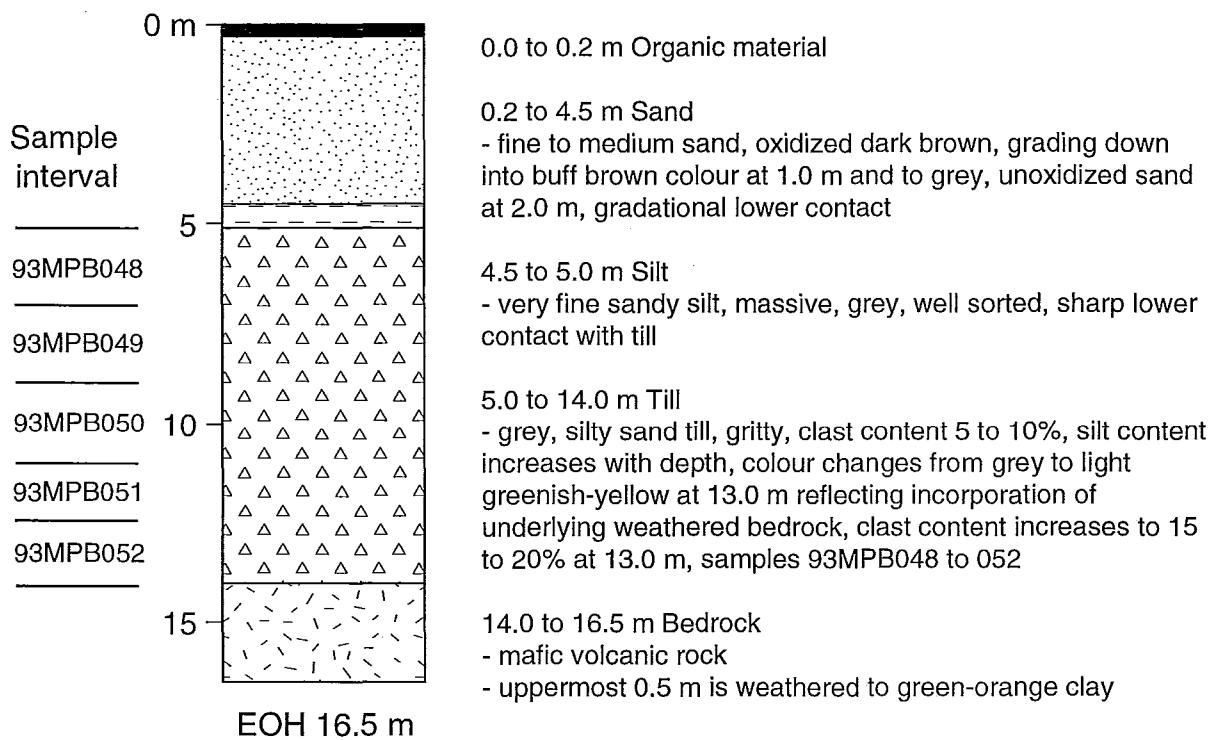

10.4 to 11.8 m Till/gravel?

- no core recovered

11.8 to 15.0 m Bedrock

- intermediate to mafic volcanic rock

HOLE C14-08

Appendix B Total sample and heavy mineral fraction weight data for GSC kimberlite and glacial sediment samples processed by Overburden Drilling Management Ltd.

Legend

TOTAL SAMPLE WEIGHT: weight (kg, wet) of entire sample

WEIGHT >2 mm MATERIAL: weight (kg, wet) of >2 mm (+10 mesh) fraction, used for pebble counts

WEIGHT <2 mm MATERIAL: weight (kg, wet) of <2 mm (-10 mesh) fraction

1-2 mm FRACTION

TOTAL WEIGHT: weight (g, dry) of the 1.0 to 2.0 mm fraction

WEIGHT NON-MAG HEAVIES: weight (g, dry) of the 1.0 to 2.0 mm non-ferromagnetic heavy mineral fraction

WEIGHT MAG HEAVIES: weight (g, dry) of the 1.0 to 2.0 mm ferromagnetic heavy mineral fraction

<1 mm FRACTION

TOTAL WEIGHT: weight (g, dry) of the <1 mm fraction

WEIGHT NON-MAG HEAVIES: weight (g, dry) of the <1 mm non-ferromagnetic heavy mineral fraction

WEIGHT MAG HEAVIES: weight (g, dry) of the <1 mm ferromagnetic heavy mineral fraction

TOTAL WEIGHT NON-MAG HEAVIES: weight of 1.0 to 2.0 mm plus <1 mm non-ferromagnetic heavy mineral fractions

TOTAL WEIGHT MAG: weight of 1.0 to 2.0 mm plus <1 mm ferromagnetic heavy mineral fractions

APPENDIX B: Total sample and heavy mineral fraction weight data for kimberlite and glacial sediment samples

Appendix D. INAA data for the <1.0 mm, non-ferromagnetic heavy mineral fraction of kimberlite and glacial sediments

| | page |
|---|---------|
| Table D.1 Lower detection limits and analytical methods | ... 117 |
| Appendix D.1 Analytical quality control data | ... 118 |
| Appendix D.2 Data listing | ... 120 |

Table D.1 Elements determined and lower detection limits for INAA of the <1.0 mm nonferromagnetic heavy mineral fraction.

| Element | Lower Detection limit |
|----------------|----------------------------------|
| Ag ppm | 5 ppm |
| As ppm | 0.5 ppm |
| Au ppb | 2 ppb |
| Ba ppm | 200 ppm |
| Br ppm | 0.5 ppm |
| Ca % | 1% |
| Ce ppm | 3.0 ppm |
| Co ppm | 1 ppm |
| Cr ppm | 5 ppm |
| Cs ppm | 1 ppm |
| Eu ppm | 0.2 ppm |
| Fe % | 0.01% |
| Hf ppm | 1 ppm |
| Hg | 1 ppm |
| Ir ppb | 10 ppb |
| La ppm | 0.5 ppm |
| Lu ppm | 0.05 ppm |
| Mo ppm | 20 ppm |
| Na % | 0.01% |
| Ni ppm | 200 ppm |
| Nd ppm | 5 ppm |
| Rb ppm | 15 ppm |
| Sb ppm | 0.1 ppm |
| Sc ppm | 0.1 ppm |
| Se ppm | 20 ppm |
| Sm ppm | 0.1 ppm |
| Sn ppm | 500 ppm |
| Sr ppm | 500 ppm |
| Ta ppm | 0.5 ppm |
| Tb ppm | 0.5 ppm |
| Th ppm | 0.2 ppm |
| U ppm | 0.5 ppm |
| W ppm | 1 ppm |
| Yb ppm | 0.2 ppm |
| Zn ppm | 50 ppm |

| Table E.1 Lower detection limits and analytical methods | ... 123 |
| Appendix E.1 Analytical quality control data | ... 124 |
| Appendix E.2 Data listing | ... 126 |

Table E.1 Analytical methods and lower detection limits for analysis of the <0.063 mm fraction.

| Element | Method | Lower Detection limit |
|----------------|--------------------|----------------------------------|
| Ag ppm | ICP-AES | 0.2 ppm |
| Al % | ICP-AES | 0.01% |
| As ppm | ICP-AES | 2 ppm |
| Au ppb | Fire assay/ICP-AFS | 2 ppb |
| Ba ppm | ICP-AES | 10 ppm |
| Be ppm | ICP-AES | 0.5 ppm |
| Bi ppm | ICP-AES | 2 ppm |
| Ca % | ICP-AES | 0.01% |
| Cd ppm | ICP-AES | 0.5 ppm |
| Co ppm | ICP-AES | 1 ppm |
| Cr ppm | ICP-AES | 1 ppm |
| Cu ppm | ICP-AES | 1 ppm |
| Fe % | ICP-AES | 0.01% |
| Ga ppm | ICP-AES | 10 ppm |
| Hg ppm | ICP-AES | 1 ppm |
| K% | ICP-AES | 0.01% |
| La ppm | ICP-AES | 10 ppm |
| Mg % | ICP-AES | 0.01% |
| Mn ppm | ICP-AES | 5 ppm |
| Mo ppm | ICP-AES | 1 ppm |
| Na % | ICP-AES | 0.01% |
| Ni ppm | ICP-AES | 1 ppm |
| P ppm | ICP-AES | 10 ppm |
| Pb ppm | ICP-AES | 2 ppm |
| Pd ppb | Fire assay/ICP-AFS | 2 ppb |
| Pt ppb | Fire assay/ICP-AFS | 3 ppb |
| Sb ppm | ICP-AES | 2 ppm |
| Sc ppm | ICP-AES | 1 ppm |
| Sr ppm | ICP-AES | 1 ppm |
| Ti % | ICP-AES | 0.01% |
| Tl ppm | ICP-AES | 10 ppm |
| U ppm | ICP-AES | 10 ppm |
| V ppm | ICP-AES | 1 ppm |
| W ppm | ICP-AES | 10 ppm |
| Zn ppm | ICP-AES | 2 ppm |

Appendix E.1 Quality control data for the <0.063 mm fraction aqua regia/ICP-AES analysis

Appendix F.1 C14 kimberlite description

B.A. Kjarsgaard
Geological Survey of Canada

Hole C14-05
Sample C14-05: 42.0m

Diatreme facies heterolithic tuffisitic kimberlite breccia

The hand sample is light green to grey in colour, with abundant limestone fragments (white, grey and light green in colour) and rarer volcanic (dark brown in colour) fragments. These country rock inclusions are dominantly 1-2 cm in size, but range from <1 to >8 cm in size and are variably coated with kimberlite groundmass material. Black kimberlite autoliths to 4 cm in size were noted, but are not common. Large (.5 - 1 cm) altered olivine grains are also conspicuous, along with rarer garnet and phlogopite crystals. A few larger pelletal lapilli can also be discerned.

Petrographic examination of a thin section from the sample reveals that the macrocryst assemblage is dominated by olivine (typically 5 - 8 mm in size) with phlogopite and garnet and rare orthopyroxene and clinopyroxene. Pelletal lapilli are quite common, and quite variable in size (mm - cm). Olivine which is typically .25 - 2 mm in size is observed in the groundmass, and also in the pelletal lapilli. All the olivine grains in the sample, regardless of size, are completely replaced by serpentine. In rare instances, olivine has been replaced by calcite and serpentine. The groundmass consists of serpentine, Fe-rich spinels with atoll textures, calcite, perovskite and apatite. Micro-crystalline diopside is locally developed.

Sample C14-05: 38.9 m

Virtually identical to that described above and is not separately described, although there appears to be additional sheet silicates (clays) related to weathering processes.

Appendix F.1 C14 area Archean bedrock descriptions

B.R. Berger
Ontario Geological Survey

Hole C-14-01: 17.5-23.0 m. From 17.5 to 20.0 m is weathered bedrock consisting of clay, rock chips and broken rock fragments. From 20.0-23.0 m, bedrock is a dark grey phaneritic basalt. It contains plagioclase phenocrysts and is similar to the bedrock from hole C14-04. There are well developed lineations on some slip faces (slickensides?) indicative of vertical movement. Magnetic susceptibility 5-20 S.I. units; average 10 S.I. units. No sample submitted for thin section.

Hole C-14-02: 38.0-40.0 m. From 38.0 to 39.8 m, bedrock is ground up bedrock, consisting of clay and broken rock fragments. From 39.8 to 40.0 m, bedrock is hard, yellow-green felsic rock that is plagioclase porphyritic. There are white plagioclase phenocrysts in a yellow-green groundmass and there is sericite on fracture faces. The rock is largely unaltered but there is trace amounts of disseminated pyrite throughout the rock. The geochemistry indicates that this is a rhyolite. Magnetic susceptibility 5-50 S.I. units with the highest spikes in the clay; the rock average 5-15 S.I. units.

Thin section description:

| | |
|-------------|-----|
| Quartz | 35% |
| Plagioclase | 40% |
| Sericite | 15% |
| Carbonate | 6% |
| Chlorite | 2% |
| Opaques | 2% |

This is felsic porphyritic flow with euhedral to anhedral quartz phenocrysts 2-5 mm in size. The plagioclase in the groundmass defines a weak preferred crystal orientation. The geochemistry agrees with the petrography.

Hole C-14-03: 8.3-11.0 m. Bedrock is a green-grey phaneritic basalt that has a granular textured fresh surface. There are quartz stringers in many places which makes this rock unsuitable for sampling. The basalt is similar to basalts from other holes in Clifford Township. Trace amounts of disseminated pyrite occur in the upper part of the drill core. No sample submitted for thin section.

Hole C-14-04: 13.6-17.0 m. Bedrock is composed of plagioclase porphyritic basalt. The rock is green, medium-grained and contains euhedral to anhedral, white plagioclase phenocrysts up to 1 cm in size (average 2-5 mm).

The basalt is massive to weakly foliated and contains weak hematite alteration.

Thin section description:

| | |
|-------------|-----|
| Plagioclase | 45% |
| Quartz | 25% |
| Epidote | 23% |
| Chlorite | 5% |
| Carbonate | 1% |
| Opaques | 1% |

The rock is a quartz-feldspar porphyry (QFP) with 40-50% phenocrysts. The feldspar are euhedral to subhedral and the quartz phenocrysts are subhedral to anhedral. Some of the quartz contains embayments of the groundmass indicating it is primary. There is no foliation or preferred crystal orientation. Original mafic phenocrysts are now altered to epidote. Very typical textures for a QFP intrusion.

Hole C-14-06: 19.0-20.0 m. Bedrock is a green foliated mafic flow. Plagioclase phenocrysts comprise approximately 5% of the rock. It is non-magnetic and contains a few widely scattered quartz veins. There is from trace to 1% pyrite on the slip faces. Magnetic susceptibility box 4 – 5-700 S.I. units; average 15 S.I. units.

Thin section description:

| | |
|-------------|-----|
| Plagioclase | 50% |
| Sericite | 28% |
| Chlorite | 13% |
| Carbonate | 7% |
| Opaques | 2% |

The rock contains 15% plagioclase phenocrysts in a very fine-grained groundmass containing plagioclase, carbonate and sericite. The plagioclase phenocrysts are euhedral and there does not appear to be any quartz in the rock. There is a weak tectonic foliation. The geochemistry indicates dacitic composition.

Hole C-14-07: 11.8 to 15.0 m. From 11.8 to 14.0 m, bedrock consists of bedrock broken into rock fragments and mud ground during drilling. The bedrock is composed of densely amygdaloidal, grey-green basalt. The amygdules are quartz filled and show a preferred elongation which is inferred to be along the foliation planes. Some of the amygdules are rimmed by hematite and there is hematite in a few stringers. There are small mafic phenocrysts in the groundmass and there is trace pyrite throughout the rock. Magnetic susceptibility 5-30 S.I. units; average 15 S.I. units.

Thin section description:

| | |
|-------------|------------|
| Plagioclase | 50% |
| Carbonate | 10% |
| White mica | 10% |
| Quartz | 10% |
| Chlorite | 10% |
| Epidote | 9% |
| Opaques | 1% |
| Titanite | trace - 1% |

Quartz, carbonate and chlorite are concentrated in amygdules but also occur in the groundmass. Some of the carbonate is botryoidal. White mica replaced some of the plagioclase laths and also occurs in the groundmass. Much of the plagioclase is trachytic textured. This is more an intermediate to mafic flow.

Hole C-14-08: 14.0 to 16.5 m. From 14.0-15.0 m, bedrock consists of clay and broken rock fragments of weathered bedrock. From 15.0 to 16.5 m, bedrock is a sausauritized plagioclase phric basalt. The rock is fine- to medium-grained and has a granular texture. The rock has a subvertical foliation and contains mafic clots. Material is similar to the bedrock in hole C14-06. Magnetic susceptibility 10-30 S.I. units; average 15 S.I. units. No sample submitted for thin section.

APPENDIX F.2 Analytical methods and lower detection limits for bedrock analysis by X-Ray Asay Labs.

| Bedrock type | Element | Method | Lower Detection limit |

Appendix H. Pebble lithology data for the 0.56 to 6.0 cm fraction

Legend

Felsic & Int intr - felsic and intermediate intrusive rock
Mafic intr - mafic intrusive rock
Met-volcs - metavolcanic rock
Ultramafic - ultramafic rock
Meta-seds - metasedimentary rock
Paleo carb - Paleozoic carbonate rock from Hudson Bay Lowlands
Kimb - kimberlite, including limestone xenoliths
Vein Qtz - vein quartz
Other/unknown - other or unidentified rock types

Note: data reported as frequency percent (%)

Appendix H. Pebble lithology data for >5.6 mm fraction of glacial sediment samples
