### LEGEND

Coloured legend blocks indicate units that appear on this map

<b>QUATERNARY</b>	<b>Qa</b>	Glacial and lacustrine sand and gravel; minor fill
	<b>Qv</b>	Alluvium, colluvium
<b>DEVONIAN</b>	<b>D</b>	LA LOCHE and FITZGERALD Formations
<b>PALEOPROTEROZOIC</b>	<b>Xag</b>	ATHABASCA GROUP: thick bedded, coarse grained, hematite quartz sandstone and pebbly sandstones; massive, locally laminated and cross-laminated; dark green, thickly laminated, silty argillite with silty cleavage; quartz-hematite veining; weathers rust color. Minor breccia
	<b>Xct</b>	CATACLASTITE: highly fractured, recrystallized gneiss with randomized fabric (little or no planar fabric) and no linear fabric; weathers rust color. Minor breccia, mylonite
	<b>Xgm</b>	AMPHIBOLITE TO GREENSCHIST-GRADE MYLONITE: well foliated, light colored mylonite to protomylonite with abundant sigma-type porphyroclasts. Protocliths include Talbot basement gneiss, Wyle Lake granite, Colli Lake granite, high-grade mylonite, Arch Lake granite, Charles Lake granite, Slave granite, and leucogranite (Note 3)
	<b>Xlg</b>	LEUCOGRANITE: weakly to nonfoliated, white to light grey to pink, muscovite-bearing, pegmatite; coarse grained to megacrystic granite; rare biotite
	<b>Xco3</b>	COLLI LAKE WHITE GRANITE: weakly to nonfoliated, white to light grey, muscovite granite, biotite granite, leucogranite. Preliminary U-Pb monazite age is 1933-1921 Ma. Occurs as sub-arc-sea bodies that intrude (XAs, Xms, Xs, and Xco2)
	<b>Xcg</b>	CHIEPEWYAN GRANITE: massive to foliated, locally moderately foliated, medium to coarse-grained pink to red granite, includes mafic xenoliths of basement gneiss and high-grade mylonites. U-Pb zircon upper intercept age is 1925-18 Ma (Note 1)
	<b>Xws</b>	WESTERN SLAVE GRANITE: massive to weakly, locally moderately, foliated, medium to coarse-grained quartz monzonite, monzonite, and granite; color varies from white to pink; small spots of garnet, biotite, hornblende, and cordierite. Locally abundant mafic or granitic dykes, and pegmatite and quartzite; paragneiss. Dykes of Slave granite (1934 Ma; Note 1) on the margin of main pluton intrude Arch Lake granite and high-grade mylonite of LLSZ
	<b>Xcl</b>	CHARLES LAKE GRANITE: massive to foliated megacrystic granite with 15-30 per cent K-feldspar megacrysts in a medium grained, biotite-rich matrix. Megacrysts have distinctive biotite inclusions. Local fine grained porphyry with 2-3 per cent disseminated, fine grained quartz. Unit is Granite F of Godfrey and Langenberg (1986). Deformed in CLSZ into amphibolite to greenschist-grade protomylonite to mylonite. Preliminary U-Pb age is 1933 Ma (Note 1)
	<b>Xtc</b>	FISHING CREEK GRANODIORITE: coarse grained, massive to weakly foliated quartz-rich granodiorite with 20-30 per cent plagioclase, 10-20 per cent subhedral K-feldspar with biotite inclusions, and 5-10 per cent biotite as small pools enclosing minor garnet. Not deformed in CLSZ; age unknown
	<b>Xpm</b>	HIGH-GRADE PROTOMYONITE: foliated quartz-feldspathic protomylonite with incident sigma-porphyrast development from K-feldspar megacrysts. Protoclith is mainly Wyle Lake granodiorite
	<b>Xnm</b>	HIGH-GRADE MYLONITE: well banded, quartz-feldspathic mylonite, protomylonite, and ultramylonite with sparsely preserved, subhorizontally stretched quartz inclusions, amphibolite parts, and ductile foldings indicative of upper amphibolite to granulite facies during shearing. Protocliths include Talbot basement gneiss, Wyle Lake granodiorite, Colli Lake pluton and Arch Lake granite (units Xco1, and Xco2 only). Variable greenschist to sub-greenschist grade overprint
<b>PRE-TECTONIC (GRANULITE-GRADE) TALBOT PLUTONIC ROCKS</b>	<b>Xal</b>	ARCH LAKE GRANITE: massive, weakly to well foliated, mylonitic granite to syenogranite gneiss with 30 to 50 per cent leucocratic, 1-2 cm K-feldspar crystals in a fine to medium-grained matrix of biotite, quartz, feldspar, and magnetite. Locally forms L-S foliations with rods of blue quartz in association with high-grade mylonite in the Charles Lake and Leland Lakes shear zones (Note 3). U-Pb zircon age is 1939 ± 2 Ma (Note 1)
	<b>Xan</b>	ANDREW LAKE GRANODIORITE: massive to well foliated biotite-hornblende granodiorite to diorite orthogneiss with 30 to 40 per cent, equant, 5-10 mm K-feldspar porphyroclasts in a medium to coarse-grained matrix of biotite, hornblende, quartz, and feldspar. Locally cut by pink Slave granite dykes. Deformed into high grade mylonite in Andrew Lake shear zone. U-Pb zircon ages are 1959 ± 3 Ma and 1962 ± 10 Ma (Note 1)
	<b>Xco2</b>	COLLI LAKE GRANITE (main phase): moderately to well foliated, lineated, mylonitic K-feldspar megacrystic biotite granite gneiss with 30 to 50 per cent leucocratic, 3rd cm K-feldspar crystals in a medium to coarse-grained matrix of biotite, chlorite, quartz, feldspar, and minor hornblende. Locally forms dip-linear L-S foliations in high-grade mylonite of the Andrew Lake shear zone (Note 3)
	<b>Xco1</b>	COLLI LAKE QUARTZ DIORITE: massive to moderately to well foliated, biotite-rich quartz diorite that intrudes the Waugh Lake Group. Preliminary U-Pb zircon age is 1971 Ma (Note 1)
	<b>Xwb</b>	WAUGH LAKE GROUP (Xwb-Xwb4) 2.01 to 1.97 Ga; Note 1
	<b>Xws</b>	Waugh Lake Schist: foliated, biotite-rich schist, phyllite, phylonite, minor quartzite; locally abundant quartz veins; minor pegmatite
	<b>Xwv</b>	Waugh Lake Volcanic Rocks: foliated, medium to coarse-grained, chlorite- and biotite-rich mafic schistose gneiss deformed at greenschist to sub-greenschist grade
	<b>Xwcg</b>	Waugh Lake Conglomerate: foliated, medium to coarse-grained, muscovite, feldspathic, pebble to granitic conglomerate; metagraywacke
	<b>Xws</b>	Waugh Lake Paragneiss: foliated, medium to coarse-grained, sericitic gneiss, schistose gneiss; minor conglomerate, chlorite-rich schistose gneiss, quartzite
	<b>Xrs</b>	RUTLEDGE RIVER GROUP 2.13 to 2.09 Ga; Note 4
	<b>Xms</b>	Mesodimentary Gneiss: large lenses of quartzite, amphibolite, and pelitic gneiss; common mineral assemblages in pelitic gneiss include biotite-garnet-sillimanite-cordierite in the Leland Lakes area (TAM14), with biotite-garnet-sillimanite common in areas to the east; locally pervasive pegmatite veins and dykes. Correlative with Rutledge River supracrustal gneisses of the northern Talbot magmatic zone (Note 4)
<b>TALBOT BASEMENT COMPLEX</b>	<b>Xa</b>	AMPHIBOLITE: well foliated, layered biotite amphibolite; local mafic granulite
	<b>Xbs</b>	SYENOGANITE GNEISS: well foliated to mylonitic, biotite-, K-feldspar-rich syenogranite gneiss. Locally intercalated with layered gneisses; pervasively intruded by medium grained pink granite dykes coplanar to fabric. A concordant U-Pb zircon age is 2138 ± 1 Ma (Note 1)
	<b>AXth</b>	HORNBLende GRANITE GNEISS: well foliated to mylonitic hornblende-bearing, white weathersing granite gneiss. U-Pb zircon age is 2080 ± 10 Ma (Note 1)
	<b>AXb</b>	LAYERED GNEISSES: well foliated, banded, mylonitic, biotite-hornblende granite to granodiorite gneiss, hornblende diorite gneiss; locally well layered, locally deformed and physically foliated; locally highly sheared straight gneiss. Pervasively intruded by medium grained pink granite, dykes, sills, and small tabular intrusions forming up to 50 per cent of some outcrops. Preliminary U-Pb zircon ages range from 2.14 to 3.2 Ga (Note 1)
	<b>AXt</b>	TOTALITE GNEISS: well foliated to mylonitic, biotite-rich tonalite gneiss with interlayered amphibolite gneiss. Locally intercalated with layered gneiss. Pervasively intruded by medium grained pink granite dykes coplanar to fabric. Zircon ages give a three spot U-Pb upper intercept age of 3078 ± 15-9 Ma (Note 1)
	<b>ml</b>	MAFIC GRANULITE

Schematic crustal cross-section illustrating the crustal geometry of the Talbot magmatic zone (TMZ) as proposed by McDonough et al. (2000). Evolution of the TMZ includes: (a) eastward dipping subduction of oceanic crust beneath the Churchill Province and development of a continental arc prior to 1970 Ma; (b) continental collision and terminal phase of crustal thickening at about 1934 Ma with continental subduction of the Buffalo Head terrane and development of a doubly vergent aluvial transpressive orogen at granulite grade; (c) continued shortening and underthrusting of Buffalo Head crust at about 1800 Ma, with amphibolite to upper greenschist grade shear zone activity at the present erosion level. Basement blocks after McNeil et al. (2000).

### NOTES

- U-Pb zircon and monazite ages of the Talbot magmatic zone (NTS 74M, 74L) range from 1.97 to 3.2 Ga. Onset of the Talbot basement complex (TBC) range is from 3.2 to 2.1 Ga (see McNeil et al., 1995; McNeil and McDonough, 1996; McDonough, 1997; McDonough and McNeil, 1997; McNeil et al., in press; McDonough et al., in press). New detrital zircon U-Pb data and zircon-thorium ratios from the Buffalo Head Terrane (BHT) in the Churchill Province (see McNeil and McDonough, 1997) are consistent with the BHT being a remnant of the Churchill Province (see McNeil and McDonough, 1997).
- Ar-40 ages for mica from the NTS 74M area cluster around 1800 Ma, and hornblende-cooling ages are about 1800 Ma (Barnes and McDonough, 1997; Barnes and McDonough, 1998; McDonough, 1997).
- Leland Lakes shear zone (LLSZ) and Charles Lake shear zone (CLSZ) are composite shear zones active under granulite to upper amphibolite facies conditions prior to ca. 1934 Ma, and later at amphibolite to greenschist and sub-greenschist facies conditions from ca. 1800 to 1900 Ma. Beyond Lake shear zone (BSLZ) is a granulite-grade mylonite zone, and is offset by about 10 km by a dextral, greenschist-grade shear zone, the Wyle Lake shear zone. The Wyle Lake shear zone is a dextral, greenschist-grade zone, dipping, upper amphibolite to granulite facies shear zone with down-dip stretching lineations and corresponding kinematic indicators. The basement complex gneisses were thrust to the east-northeast in a dextral-oblique sense over Andrew Lake granodiorite and Colli Lake granite. This displacement to the east into the Colli Lake area was accompanied by about 10 km of extension in the eastern portion of the pluton. The Bonny Fault is a brittle fault with approximately 4.5 km of lateral offset (see McDonough et al., 1993; McDonough et al., 1994; McDonough et al., 1996; Fier and McDonough, 1996; Schatnez and McDonough, 1996; Grover et al., 1997; McDonough, 1997; McDonough et al., in press).
- Mesodimentary gneiss units Xms occur as enclaves within TBC gneisses, and as rafts within plutonic units. These gneisses are correlative with 2.13 to 2.09 Ga supracrustal gneisses of the Rutledge River basin (Barnes and McDonough, 1994), and form a cover sequence deposited on gneisses of the Talbot basement complex (McDonough et al., in press).
- For discussion of mineral occurrences see McDonough and Abernethy (1996), McDonough (1997) and references therein.
