

In 2004 and 2005, Fugro Airborne Surveys completed nine multi-sensor airborne geophysical surveys in the central region of British Columbia for the Geological Survey of Canada, the British Columbia and Yukon Chamber of Mines, Yukon First Nation, and five industry partners, including Seenergy Resources Inc., Yakoski Met Minerals, 150, Richfield Ventures Corp, GWR Resources Inc. and Earth Resources Ltd. The Geological Survey of Canada provides super-velocity airborne magnetic quality control. The purpose of the surveys was to obtain quantitative gamma-ray spectrometric and aeromagnetic data. The surveys were flown over two seasons, from September 18 to November 17 2004 and June 15 to August 8, 2005 using ASAR 350-82 and 350-83 helicopters, C-GECL and C-FGSC.

**Gamma-ray Spectrometric Data**

The airborne gamma-ray measurements were made with an Exploration GREGO gamma-ray spectrometer using nine  $102 \times 102 \times 406$  mm NaI (Ti) crystals. The main detector array consisted of eight crystals (total volume 33.6 litres). One crystal (total volume 4.2 litres), shielded by the main array, was used to detect variations in background radiation caused by atmospheric radon. The system constantly monitored the natural potassium peak for each crystal, and using a Gaussian least squares algorithm, adjusted the gain for each crystal.

Potassium is measured directly from the 1460 keV gamma-ray photons emitted by  $^{40}\text{K}$ , whereas uranium and thorium are measured indirectly from gamma-ray photons emitted by daughter products ( $^{214}\text{Pb}$  for uranium and  $^{208}\text{Tl}$  for thorium). Although these daughters are far down their respective decay chains, they are assumed to be in equilibrium with their parents, thus gamma-ray spectrometric measurements of uranium and thorium are referred to as equivalent uranium and equivalent thorium, i.e. eU and eTh. The energy windows used to measure potassium, uranium and thorium are:

Potassium ( $^{40}\text{K}$ ) 1300 - 1500 keV  
 Uranium ( $^{234}\text{Bq}$ ) 1600 - 1800 keV

Gamma-ray spectra were recorded at one-second intervals at a planned mean clearance of 130m or 50m depending on the survey area and an air speed of 125km/hr. The total, potassium, uranium and thorium spectra were recorded using a 2048 channel, 256 channelized, 1024 channel processing; the spectra were energy calibrated, and counts were accumulated into the windows described above. Counts from the radon detectors were recorded in a 1000 - 1800 keV window and recorded at energies greater than 3000 keV was recorded in the cosmic window. The window data were then used to calculate dead time and background levels. Corrections for the background radioactivity of the aircraft and atmospheric radon decay products. The window data were then corrected for spectral scattering in the ground, air and detectors. Corrections for divisions of counts from the planned survey area were made. Potassium, uranium and thorium, using factors prior to conversion to ground concentrations of potassium, uranium and thorium, using factors determined from flights over a calibration range near Ottawa.

Potassium 57.3 cps/% (2004) 58.9 cps/% (2006)  
Uranium 6.7 cps/ppm (2004) 8.4 cps/ppm (2006)  
Thorium 3.6 cps/ppm (2004) 3.7 cps/ppm (2006)

Corrected data were filtered and interpolated to a 100m grid for the 1:250 000 scale maps and to a 50m grid for the 1:200 000 and 1:50 000 scale maps. The results of an airborne gamma-ray spectrometer survey represent the average surface concentrations that are influenced by varying amounts of outcrop, overburden, vegetation cover, soil moisture and surface water. As a result, the measured concentrations are usually lower than the actual bedrock concentration. The total air absorbed dose rate in nanograys per hour was produced from measured counts between 410 and 2810 keV.

**Magnetic Data**  
The helicopter was equipped with a Scintrex CS-2 cesium vapour magnetic sensor mounted in a HM1 high-resolution single sensor stinger mounted system. The system recorded readings every 0.1 seconds with a noise level of less than 0.01 nT. Magnetic interferences caused by aural maneuvers were compensated using an RMS AADC1 Magnetic compensator. Diurnal variations and GPS fluctuations were recorded using a Fugro CF1 base station.

After editing the survey data, the intersections of traverse and control lines were determined and the differences in the magnetic values were computed, analyzed and manually verified to obtain the leveling network. The International Geomagnetic Reference Field was calculated and removed using a fixed date of August 2, 2005 and an altitude of the differentially corrected GPS height for each data point. The corrected magnetic data was interpolated to a 50m grid using a minimum curvature algorithm. The first vertical derivative grid was calculated from the corrected total magnetic intensity grid using a FFT based frequency domain filtering algorithm.

**Positional Data**  
Line spacing and direction for survey and control lines were selected for each block to ensure the best intersection of local geological features. Terrain clearance was monitored by radar altimeter. Positional data were recorded using a dual frequency Novatel Millennium system. GPS groundstation data were combined with airborne GPS data to produce differentially corrected positional data with an accuracy of 2 to 5 m.

**Data Presentation**  
Colour levels and contours were calculated for each grid and combined with map surround information to create postscript plot files, which were plotted using HP DesignJet colour plotters.
