Abstract

Vitrinite reflectance on the 19 samples from the Mackenzie Corridor yielded the following 4 maturity groups. Four samples from the Redstone River and Old Fort areas were immature. Five samples from the Sigma line W4, Redstone River and Keele River areas were mature to overmature. Four samples from the Sigma line W6 & 7 areas were marginally mature. Four samples from the Cadillac Mine were overmature. Two samples did not produce any reflectance values.

Introduction

Nineteen polished, whole rock stubs (pellets) were analysed for Vitrinite reflectance (VR). The stubs were prepared from material originally sampled from mostly outcrops in the Mackenzie Corridor by D. K. Norris, GSC Calgary between 1976 and 1986 (Table I, Figure 2). The stubs provided by GSAC were prepared and polished for incident light photometric microscopical analysis. This requires a level scratch free surface when viewed at about 640 magnification. The analysis was run on a Zeiss microscope system interfaced to a microcomputer to record and display the photometric data.

General Remarks

Typically, vitrinite reflectance analyses on whole rock preparations yield less than optimum measurable particles. Most of these samples provided fewer readings than typically needed for a thermal maturity assessment (Table II and Appendix II); with the exception of those from the Cadillac Mine. Also, since most of the samples are from outcrops they are less than ideal because of oxidation by weathering, the association between sulphides and vitrinites also may have affected some reflectance measurements (Table 2).

Results

The vitrinite reflectance data for the 19 samples can be grouped into 4 maturity ranges (Table II).

Four samples (at sample map locations #'s 1 & 2) from the Redstone River and Old Fort areas produced values (0.34-0.47) in the immature range (Appendix I) which is at the lignite to subbituminous coalification level. This group is Cretaceous age with (#1) coming from the East Fork Fm and (#2) from the Little Bear Fm (Table III).

Four samples (#3 to 6) from the Sigma line W6 & 7 areas produced values (0.48-0.58) which are just at the start of the mature range which is in the subbituminous coalification level. This group comes from a Tertiary conglomerate and sandstone unit.

Five samples (#7 to 12) from the Sigma line W4, Redstone River (different map area) and Keele River areas produced values (1.04-1.69) in the upper mature to overmature range which is about in the medium to low volatile matter coalification level. Sample #12 from the Keele River did not yield any data. This group comes from an upper Devonian sandstone unit.

Sample (#13) from the Cadillac Mine area did not yield any data. It came from the Silurian Delorme Fm.

Four samples (#14) from an adjacent area also labelled Cadillac Mine produced values (2.33-2.68) which are very overmature and in the anthracite coalification level. This group comes from the middle Devonian Nahanni Fm.

* Note: Some of the area descriptions of where samples were collected do not seem to match the locations where those samples plot on the map based on the latitude/longitude coordinates. Because more than 20 years have elapsed since the sampling was done it has not been possible to settle the discrepancy. The coordinates are accepted as correct.
