DESCRIPTIVE NOTES

INTRODUCTION

This Surficial Geology Map of NTS 94-O/9 (Canadian Geoscience Map 123) is the product of collaboration between the Geological Survey of Canada and the British Columbia Ministry of Energy, Mines and Natural Gas as part of the Geo-mapping for Energy and Minerals Program (GEM-Energy Yukon Basins Project. The accompanying geodatabase includes field observation points and field photos, landform features as lines, and surficial geology unit polygons. The map and geodatabase are essential baseline geoscience information for a range of potential end-users including resource explorationists, geotechnical engineers, land-use managers, terrestrial ecologists, archaeologists, geoscientists and communities in northern British Columbia. By providing new insight into the distribution and origins of surficial earth materials, CGM 123 will help to reduce the economic costs and risks associated with the sustainable development of energy and mineral resources in NTS 94-O/9. Environmental impact assessments for new access roads, work camps, well pads, pipeline and power transmission line corridors, water storage and waste management systems and other infrastructure will benefit from the geoscience information presented here. By identifying areas prone to geological hazards (e.g., landslides, permafrost, flooding), CGM 123 will also help to protect natural resources, infrastructure and communities vulnerable to climate change in Canada's north.

APPROACH TO SURFICIAL GEOLOGY MAPPING

Terrain mapping and field-based benchmarking studies have led to a better understanding of the regional distribution of surficial deposits, permafrost, landslides and other geomorphic processes in the NTS 94-O/9 map area (Huntley and Hickin, 2010; Huntley et al., 2011a-b). Surficial earth materials and landforms were interpreted using a combination of stereo-pair air photos (BCB97010, 15BCB97015, 15BCB97020, 15BCB97075 and 15BCB97088 series), LANDSAT 7 satellite imagery (http://glovis.usgs.gov/ [URL 2011]) and Shuttle Radar Topography Mission digital elevation models (http://dds.cr.usgs.gov/srtm/ [URL 2011]). The base map was generated from CANVEC shape files (http://geogratis.cgdi.gc.ca/geogratis/ [URL 2011]). Surficial geology polygons and landform line symbols were digitized using commercially available computer software packages (Global Mapper, ArcMap and ArcGIS) and compared to published maps, reports and archived digital data (e.g., Stott and Taylor, 1968; Bednarski, 2003a-C; Clement et al., 2004; Bednarski, 2005a-b; Tommelein and Levson, 2008; Demchuk, 2010). The geodatabase accompanying this map conforms to the Science Language for the Data Management component of the GEM Geological Map Flow process (cf. Huntley and Sidwell, 2010; Huntley et al., 2011a; Deblonde et al., 2012).

Fieldwork was undertaken in 2009 and 2010 to ground truth surficial geology polygons interpreted from air photos and satellite imagery, and to gather characteristics that could not be determined through remote predictive mapping. Earth materials were defined on the basis of facies and landform associations, texture, sorting, colour, sedimentary structures, degree of consolidation, and stratigraphic contact relationships at field stations and remote observations from helicopters. The distribution of glacial and non-glacial landforms is depicted on the surficial geology map. Map units in the Legend are presented chronostratigraphically and include organic deposits, alluvial, colluvial, eolian, glaciolacustrine and glaciofluvial sediments, tills and areas of bedrock.

INFERRED GEOLOGICAL HISTORY

The distinctive landscape of NTS 94-O/9 is largely a product of underlying bedrock and geological structures, with ornamentation by the Late Wisconsinan Laurentide Ice Sheet. The Etsho Plateau is underlain by conglomerate, sandstone and carbonaceous shale of the Upper Cretaceous Dunvegan Formation. In the northwest corner of the map sheet, the Stanislas Creek headwaters are underlain by undifferentiated clastic bedrock (Lower Cretaceous Fort St. John Group, Stott and Taylor, 1968).

Topography and drainage patterns were greatly modified during the phase of maximum ice cover (>18 °C ka BP or >21.4 calendar ka BP). Unconsolidated sediment thicknesses in excess of 2-5 m are observed in major valleys and it is suspected that similar drift thicknesses blanket bedrock (unit R) across the map area. Silt- and clay-rich Laurentide tills have low clast contents (<20%) of proximally derived Cretaceous siliciclastic sedimentary rocks and distal igneous and metamorphic clasts from the Canadian Shield, hundreds of kilometres to the northeast. Drumlinized ridges up to several hundred metres in length suggest clay-rich tills (unit Ts) were deposited beneath active, rapidly flowing warm-based glacial ice (Huntley and Hickin, 2010; Huntley et al., 2011b). Small lake basins were excavated by erosion and ice-thrusting as Laurentide ice and subglacial meltwater scoured and deformed older glacial deposits and weak bedrock. Multiple directions and generations of ice flow are preserved in streamlined till across the map area. In the southeast of the map area, ice flow was toward the southwest, whereas in the northern half of the map area, ice flow was deflected west by the sloping flank of the Etsho Plateau. Together, this suggests diverging ice flow prior to the onset of deglaciation.

Deglaciation began sometime after 18 °C ka BP (or >21.4 calendar ka BP) and ended before 10 °C ka BP (ca. 12 calendar ka BP), with the retreating active Laurentide Ice Sheet, stagnant ice masses in lowlands, glaciofluvial outwash and landslide debris blocking and reordering regional drainage. The mapped distribution of major moraine ridges (unit Tm) implies that ice over the Etsho Plateau retreated to the northeast into the Pettitot River valley (Huntley and Hickin, 2010). Some large end moraines are deformed and streamlined suggesting that receding lobes remained active during retreat and occasionally rapidly advanced. Minor moraine ridges draped by drumlins in cross-cutting patterns and are interpreted as crevasse fillings and squeeze moraines deposited shortly after drumlinization ended, or as ice retreated from the map area (Huntley et al., 2011b). Hummocky till (unit Th) is found in proximity to short segments of subaerial subglacial meltwater channels and eskers, indicating that bodies of stagnant glacier ice remained in lowland areas west of the Maxhamish Escarpment. Eskers (unit GFr) are composed of hummocky till and glaciofluvial gravelly sand, and likely exploited pre-existing cross-valley meltwater channels containing ice sheet or stagnant ice bodies (Huntley et al., 2011a; b).

Post-glaciation (10 °C ka BP or ca. 12 calendar ka BP to present), changes in regional base-level led to episodes of channel incision and aggradation, resulting in the formation of erosional alluvial terraces along most stream and river valleys. In the early Holocene, pulses of fluvial terrace building followed initial valley incision by the Liard and other major rivers. Most streams and rivers have alluvial fans (unit Af) and terraces (unit At) <5 m above active floodplains (Ap) consisting of gravel overlain by silt and sand. Poorly drained clay-rich till on the plateaus and glaciolacustrine sediments in lowland areas are covered by extensive postglacial peat deposits (unit Owb), ferns (unit Owf) and undifferentiated wetlands (unit O). Discontinuous permafrost is sporadically encountered in glaciolacustrine and some peat deposits. Charcoal, observed in dug pits on alluvial terraces, suggests forest fires may have contributed to periods of landslide activity on slopes and local fluvial aggradation. Landslides and colluvial deposits (units Cv, Cb) are common where bedrock outcrops form escarpments, and where shale or fine-grained glacial deposits are exposed along steep cutbanks. Stream networks and wetlands draining plateau watersheds are disrupted by beaver activity and, to a lesser extent, by roads and infrastructure where they cross streams, rivers and organic deposits (Huntley and Hickin, 2010; Huntley and Hickin, 2011a-b).

ACKNOWLEDGMENTS

Canadian Geoscience Map 123 is an output of the Geo-Mapping for Energy and Minerals Yukon Basins Project managed by Carl Ozyer and Larry Lane (GSC-Calgary). The assistance of Robert Cocking, Sean Eagles, Vic Dohar, Mike Sipsuin, Scott Tweedy and Martin Legault (NRCan Scientific Publishing Services) was greatly appreciated throughout the map-making process. A critical review of CGM 123 was provided by Ron DiLabio (GSC-Ottawa).

Abstract

Canadian Geoscience Map 123 depicts the surficial geology over some 790 km² covered by the Trail Lake map sheet (NTS 94-O/09), in northeastern British Columbia. Here, the Etsho Plateau lies within the Pettitot River watershed and is drained by east-flowing Gote Creek, and northward by Dilly and Yesshadle creeks. To the north of the plateau, the Stanislas Creek drains northeast into the Pettitot River. Bedrock is mantled by unconsolidated earth materials dating to the Late Pleistocene (Late Wisconsinan Glaciation, > 29 ka to ca. 10 ka) and non-glacial Holocene (ca. 10 ka to present). Deposits of till, green on the map, are generally suitable for placement of infrastructure. Glaciofluvial and eolian deposits with mineral aggregate, and groundwater potential are coloured orange and buff. Slopes disturbed by landslides, debris flows and rock falls appear brown and pink. Glaciolacustrine and organic deposits with sporadically discontinuous permafrost are coloured purple and grey. Alluvial deposits prone to flooding, erosion, and sedimentation appear yellow on the map.

Résumé

La Carte géoscientifique du Canada 123 illustre la géologie des matériaux superficiels d'un territoire d'environ 790 km² couvert par le feuillet cartographique de Trail Lake (SNRC 94–/09), dans le nord-est de la Colombie-Britannique. Ici, le plateau d'Etsho se situe dans le bassin versant de la rivière Pettiot et est drainé par le ruisseau Gote vers l'est ainsi que par les ruisseaux Dilly et Yesshadle vers le nord. Au nord du plateau, le ruisseau Stanislas draine le territoire vers le nord-est pour aboutir dans la rivière Pettiot. Le socle rocheux est couvert de matériaux terrestres non consolidés remontant au Pléistocène supérieur (Glaciation du Wisconsinien supérieur, de > 25 ka à env. 10 ka) ainsi que de matériaux non glaciaires de l'Holocène (d'env. 10 ka jusqu'à nos jours). Les dépôts de till, de couleur verte sur la carte, sont généralement propices à l'établissement de l'infrastructure. Les dépôts fluvioglaciaires et éoliens, qui recèlent un potentiel en minéraux, en agrégats et en eau souterraine, sont figurés par les couleurs orange et chamois. Les versants dérangés par des glissements de terrain, des coulés de débris et des chutes de blocs sont représentés en brun et en rose. Les dépôts glaciolacustres et organiques, qui renferment sporadiquement du pergélisol discontinu, sont représentés en violet et en gris. Les dépôts alluviaux sujets aux inondations, à l'érosion et à la sédimentation apparaissent en jaune sur la carte.

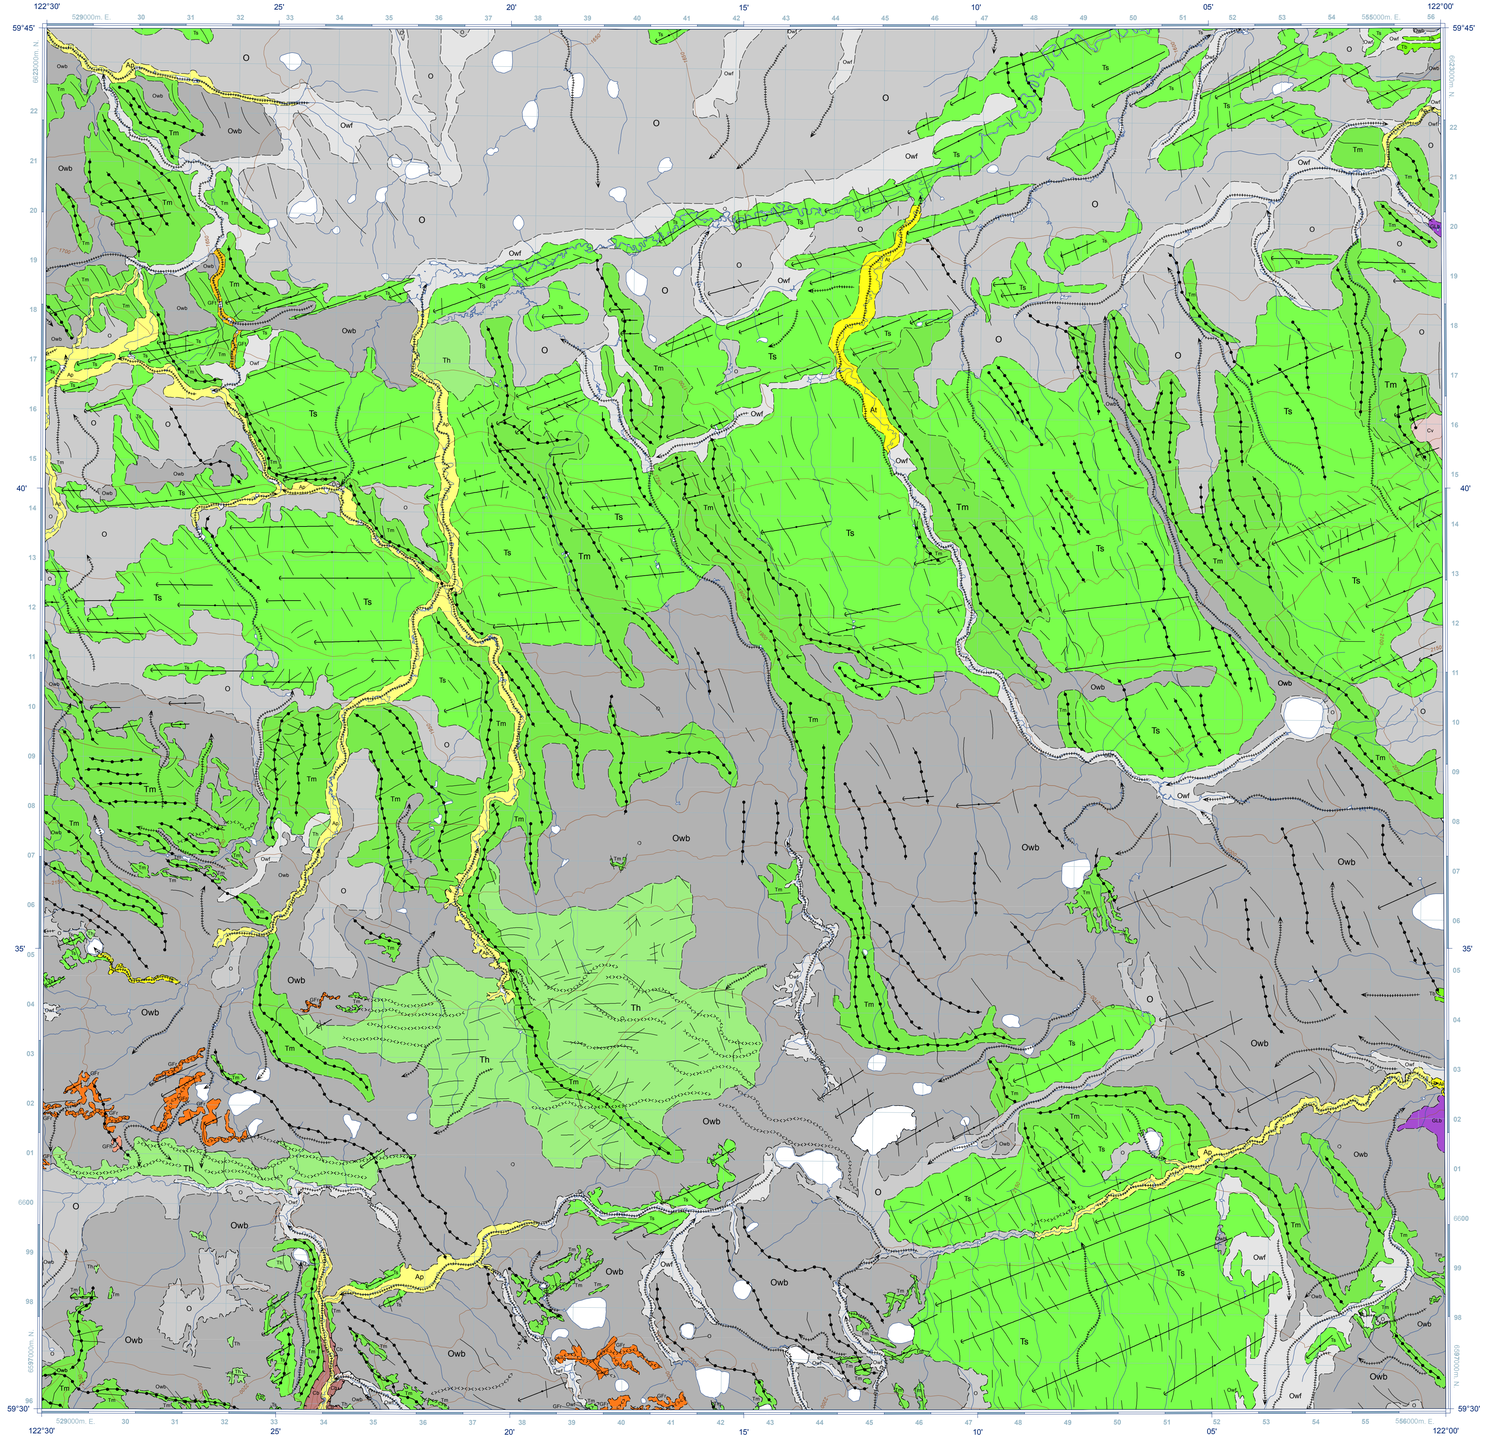
CANADIAN GEOSCIENCE MAP 123

SURFICIAL GEOLOGY

TRAIL LAKE

British Columbia

1:50 000



Holocene earth materials and landforms

Organic Deposits

Owb

Peat bogs: fibric to humic organic matter; massive to stratified accumulations; generally greater than 2 m thick; confined to topographic depressions or level areas; underlain by poorly drained till, glaciolacustrine and other unconsolidated sediments; formed by decomposition of plant material in wetland areas; bogs with sporadically discontinuous permafrost and thermokarst depressions potentially unstable if organic material is disturbed or removed.

Owf

Fens: fibric organic matter; massive to stratified; generally greater than 2 m thick; confined to topographic depressions, level areas and meltwater channels; underlain by poorly drained till, glaciolacustrine and other unconsolidated sediments; formed by decomposition of plant material in wetland areas; fens are prone to flooding following drainage damming by beaver activity.

O

Undifferentiated peat bogs and fens: humic to fibric organic matter; massive to stratified accumulations; generally greater than 2 m thick; confined to topographic depressions, level areas or channels; underlain by poorly drained till, glaciolacustrine and other unconsolidated sediments; formed by decomposition of plant material in wetland areas; bogs may contain sporadically discontinuous permafrost and thermokarst depressions; potentially unstable if disturbed or removed during development.

Alluvial deposits

At

Alluvial terraced sediments: boulders, gravel, sand and silt; generally massive to planar stratified; well to rapidly drained; greater than 2 m thick; may contain interbedded debris flows and buried organic material; underlain by outwash, till or bedrock; transported and deposited by modern rivers, streams and creeks; subject to rare flooding; potential source of aggregate; land use activities may adversely affect stream courses and conditions, and impact fish and wildlife resources.

Ap

Alluvial floodplain sediments: gravel, sand and silt; massive, trough crossbedded, rippled-bedded, planar stratified; well to rapidly drained; greater than 2 m thick; underlain by till or bedrock; transported and deposited by modern rivers, streams and creeks; subject to seasonal flooding; land use activities may adversely affect stream courses and conditions, and impact fish and wildlife resources.

Colluvial deposits

Cv

Colluvial veneer: clast-supported diamictons and rubble; massive to stratified, poorly-sorted; well to rapidly drained; deposits less than 2 m thick; landslide headscarps range from 300 m to 10.5 km; formed by the weathering and down-slope movement of earth materials by gravitational processes; bedrock and unconsolidated debris on slopes above 10-15° with greater than 5 m relief prone to mass-wasting; rock falls, topples, rock slides and debris flows occur where shale, sandstone and carbonate strata is exposed close to the surface; retrogressive rotational debris slides, debris flows and slumps occur in glaciolacustrine sediments and outwash containing sporadically discontinuous permafrost; where ground ice is found slope failure can occur on surfaces less than 5°; slope instability could present major problems for construction in some areas.

Cb

Colluvial blanket: clast-supported diamictons and rubble; massive to stratified, poorly-sorted; well to rapidly drained; deposits greater than 2 m thick; landslide headscarps range from 300 m to 10.5 km; formed by the weathering and down-slope movement of earth materials by gravitational processes; bedrock and unconsolidated debris on slopes above 10-15° with greater than 5 m relief prone to mass-wasting; rock falls, topples, rock slides and debris flows occur where shale, sandstone and carbonate strata is exposed close to the surface; retrogressive rotational debris slides, debris flows and slumps occur in glaciolacustrine sediments and outwash containing sporadically discontinuous permafrost; where ground ice is found slope failure can occur on surfaces less than 5°; slope instability could present major problems for construction in some areas.

Late Pleistocene earth materials and landforms

Glaciolacustrine deposits

GLb

Glaciolacustrine blanket: silt and clay with subordinate sand, gravel and diamicton; massive or rhythmically interbedded; slump structures and dropstones locally present; poor to moderately drained; generally greater than 2 m thick; kettle lakes and irregular topography underlain by bedrock, till and outwash; transported by and deposited from sediment-laden meltwater, subaqueous gravity flows and thermal melting of ice in proglacial lakes; where sporadically discontinuous permafrost is, or was present, glaciolacustrine sediments may be subject to thermokarst processes; generally less than 5° are potentially unstable and prone to landslides and debris flows.

Glaciofluvial deposits

GFh

Kames and hummocky outwash: boulders, cobbles, pebble-gravel, sand, silt and diamicton; generally massive to stratified, some slump structures; moderately to well-drained; greater than 2 m thick; irregular hummocks and kettled topography; in contact with, and overlying till units, outwash and glaciolacustrine sediments; deposited by rivers and streams flowing from, or in contact with glacial ice; potential source of groundwater and granular aggregate when material is gravel rich.

GFr

Esker ridges: boulders, cobbles, pebble-gravel, sand, silt and matrix-supported diamicton; generally massive to stratified, some slump structures; moderately to well-drained; greater than 2 m thick; range from 100 m to 8.8 km in length; in contact with, and overlying till units, outwash and glaciolacustrine sediments; deposited by subglacial meltwater in contact with glacial ice; potential source of groundwater and granular aggregate when material is gravel rich.

GFt

Outwash terraces: boulders, cobbles, pebble-gravel, sand, silt and matrix-supported diamicton; generally massive to stratified, some slump structures; moderately to well-drained; greater than 2 m thick; terrace scarps range from 100 m to 6 km in length; in contact with, and overlying other till units, outwash and glaciolacustrine sediments; deposited by meltwater confined to proglacial channels and spillways; potential source of groundwater and granular aggregate when material is gravel rich.

Till deposits

Tb

Till blanket: sand, silt and clay-rich diamictons; massive, matrix-supported and compact; clast contents less than 20% and contain sub-rounded granitic erratic boulders with sources on the Canadian Shield; moderately to well-drained; greater than 2 m thick mantling bedrock and older glacial deposits; transported and deposited by the Laurentide Ice Sheet directly through lodgement, basal meltout, glacigenic deformation of sediment beneath active, warm-based ice and in situ melting from stagnant cold-based ice; stable terrain, generally suitable for infrastructure placement.

Th

Hummocky till: sand and silt-rich diamictons; massive to stratified, matrix- and clast-supported; clast contents less than 20% and contain sub-rounded granitic erratic boulders with sources on the Canadian Shield; moderately to well-drained; greater than 2 m thick; drapes till and other glacial deposits; deposited by in situ melting from stagnant cold-based ice and modified by meltwater; evidence for ice collapse includes slump structures, kettle lakes and irregular topography; potential source of aggregate when material is gravel rich; generally suitable for infrastructure placement.

Tm

Moraine ridges: sand, silt and clay-rich diamictons; massive, matrix-supported; clast contents less than 20% and contain sub-rounded granitic erratic boulders with sources on the Canadian Shield; moderately to well-drained; greater than 2 m thick; minor moraines less than 1 km long and 5 m high; major moraines up to 12.5 km in length and 10 m high; ridges drape bedrock and older glacial deposits; minor moraines include crevasse-fill ridges and small recessional push moraines; major ridges features are large recessional end moraines and ice-thrust ridges; generally suitable for infrastructure placement.

Ts

Streamlined till: silt and clay-rich diamictons; massive, matrix-supported and compact; clast contents less than 20% and contain sub-rounded granitic erratic boulders with sources on the Canadian Shield; moderately well-drained; greater than 2 m thick mantling bedrock and older glacial deposits; drumlins and fluted till ridges typically under 1 km long but can exceed 9 km in length; generally less than 50 m wide and 20 m high; formed beneath the Laurentide Ice Sheet directly through lodgement, basal meltout, glacigenic deformation of sediment beneath rapidly-flowing warm-based ice; generally suitable for infrastructure placement.

- Geological boundary (Confidence: approximate)
- Major moraine ridge (unspecified)
- Other moraine ridge (unspecified)
- Esker ridge (sense: unknown or unspecified)
- Drumlin ridge
- Major meltwater channel scarp
- Minor meltwater channel central axis (unspecified; sense: known)
- Station location (ground observation or stratigraphic section)
