REPORT

of the

ORE DRESSING AND METALLURGICAL LABORATORIES.

Investigation No. 1076.

Amalgamation and Cyanidation of a Gold Ore from Negus Mines Limited, Yellowknife, N. W. T.

Report of the Ore Dressing and Metallurgical Laboratories.

Report No. 1.

Amalgamation and Cyanidation of a Gold Ore from Negus Mines Ltd., Yellowknife, N. W. T.

<u>Shipments:</u> Four lots of ore were received in July and August, 1941. No. 1 Lot of 10 lbs. No. 2 \oplus 19 lbs. No. 3 - $6\frac{1}{2}$ lbs. No. 4 - $6\frac{1}{2}$ lbs. The shipments were from Mr. J. G. McNiven, Manager, Negus Mines, Ltd., and were consigned to Mr. W. H. A. Timm, Mill Supt., Negus Mines, who superintended the test work in the Ore Dressing Laboratories. **Preva**ously, two shipments of ore had been received from the Negus Mine and the test work is covered in Investigations Nos. 742 and the Report dated May 29, 1940 of the Department.

Location of the Property: - The property of Negus Mines Limited from which the present shipment was received is situated on the West shore of Yellowknife Bay, Yellowknife Area, N. W. T.

Sampling and Analysis: - After crushing, cutting and grinding by standard methods, representative samples of the shipments were obtained which assayed as follows: -

	MIL.	a series	Lot No. 1	# 2	#3	#4
Au	oz/ton		1.53	1.11	1.00	0.16
Ag	oz/ton		0.54	0.48	0.59	0.32

Characteristics of the Ore: - Engineers' Report No. 817-2.

Sample - The sample of gold ore from Negus Mines Limited, Yellowknife, N. W. T., was received by the Division of Metallic Minerals on July 29, 1941. Six polished sections were prepared and examined miscroscopically for the purpose of providing a short description of the character of the ore.

Gangue - The gangue consists of rather fine-textured gray quartz with stringers of carbonate (calcite).

the Pages 7 2 ping and Mobaldurgian.

s. representative sarbles

Metallic Minerals -

STOP'S

The metallic minerals present in the sections are, in their order of abundance, pyrite, arsenopyrite, sphalerite, chalcopyrite, stibnite, and native gold.

Pyrite is disseminated in the quartz as rather small grains which locally are sufficiently abundant to form irregular stringers of the mineral. Arsenopyrite occurs in considerably less quantity but is common; it is usually present as small grains in the quartz but is often associated with pyrite. Occasional grains of sphalerite and rather rare grains of chalcopyrite occur in the quartz associated with carbonate, as do comparatively rare small grains of a mineral regarded as stibuite.

Native gold is present as small irregular grains in quartz, and as grains against the pyrite crystals. No gold was seen to occur within the sulphides.

Conclusion - be wore obtained which addayed

In view of the refractory nature of part of the gold contained in this sample (as proved by test work) it would seem almost certain that the gold seen in the sections represents only that which is comparatively easily extractible. No tiny gold grains which might cause difficulty in treatment were observed in the pyrite or arsenopyrite. It is therefore probable that the refractory portion of the gold in this sample is present in either or both of the sulphides in submicroscopic form.

Investigative Work: -

This procedure generally followed the flowsheet of the Negus Mill as far as was practicable in the small scale test work. The ore was ground in cyanide and the pulp passed through a Denver gold jig and the jig overflow over the blankets. The combined concentrates were reground and amalgamated and the amalgam residue added to the blanket tailings. This product was agitated in the cyanide grinding solution for 24 hours. The work showed that part of the gold was refractory to cyanidation, the cyanide residue assaying from 0.06 Au oz/ton to 0.24 Au oz/ton generally depending on the fineness of the grinding used. Superpanning and Infrasizing tests on this residue gave results showing that this refractory gold generally was contained in the sulphides.

Results of the test work follow: -

Page - 3.

Test No. 1 on Lot No. 2.

In this test the procedure followed the Negus flow-sheet. The ore was ground in cyanide to pass 87.4 % minus 200 mesh. The pulp was then passed over a jig and blankets and the combined concentrates reground and amabgamated. The amalgam residue was added to the blanket tailings and agitated in cyanide solution for 24 and 48 hours.

After grinding in cyanide of 1 lb. NaCn per ton strength the pulp was filtered, washed and sampled. The residue assayed 0.91 Au oz/ton giving an extraction of 18.0 % of the Au in the cyanide grind.

on No. 2 Head .

In this test a Wilfley table was inserted in the grinding circuit. The pulp from the amalgam tails and blk. tails was passed over a Wilfley table and the table concentrate reground in cyanide to pass 99 % -325 mesh. It was then added to the table tailings and divided into three portions prior to agitation. In #A 0.03 lbs of fuel oil was added. In #B the product wasoacrated in a lime pulp for 4 hours prior to agitation. In #C straight cyanidation was used. Otherwise the test followed the Negus flow-sheet. The primary grind was 62.0% - 200 mesh.

- Summary and Conclusions -

The test work on the present ore shipments generally followed quite closely the flow-sheet of the present Negus Mill. The ore was ground in cyanide, to different degrees of fineness and the pulp passed through a Denver gold jig with the jig overflow passing over blankets. The combined jig and blanket concentrates were reground and amalgamated. The amalgam residue was added to the blanket tailings and agitated in the cyanide grinding solution. In addition, flotation concentrations were made on several of the cyanide residues.

By this method cyanide residues of 0.10, 0.15, 0.14 and 0.95 Au oz/ton from sample lot Nos. 1, 2, 3, and 4 were obtained. The grinds were 87.4 %, 86.2 %, 70.2 % and 76 % minus 200 mesh.

On sample No. 2, when a Wilfley table was included in the grinding circuit and the resulting table concentrate reground in cyanide to 99 % - 325 mesh, and added to the table tailings prior to agitation, cyanide residues of 0.08 Au oz/ton were obtained as shown in test No. 4. Flotation concentration of the cyanide residue followed by regrinding and cyanidation of the resulting concentrates gave an additional extraction of 0.04 Au oz/ton in test No. 5 on Sample No. 2.

In the Infrasizer test on the cyanide residue it was only in the very finest particles, that there was any appreciable reduction in the residual gold. This result was confirmed by a superpanner test on the residue from No. 2 sample.

Assays of the pregnant solution disclosed that a comparatively large amount of Ni salt was present. The reducing power of the solutions was low and showed no fouling.

The test work on the present shipments showed no appreciable difference in the refractory character of one from that of the previous report dated May 1940. The increase in the value of the cyanide residues and the consequent lowering of the Au extractions indicated that a larger percentage of the gold is in refractory sulphides. Concentration of these sulphides and fine grinding will reduce this amount somewhat, but a portion of the gold is so refractory that only concentration of the residue followed by reasting and cyanidation of the calcine will extract this remaining gold.
