

~~GASOLINE SURVEYS FOR SEVEN SUMMERS~~

BUREAU OF MINES

MINES AND GEOLOGY BRANCH

DEPARTMENT OF MINES AND RESOURCES

P. V. Rosewarne, H. McD. Chantler and P. B. Seely

OTTAWA, CANADA

A study of the gasoline sold in Canada during the summer has been made annually since 1933 at the Fuel Research Bureau of Mines. Samples from gasoline obtained have been prepared between 1939 and 1946 and including 1938(1). The publication of these reports was discontinued during the war although the Laboratories continued to take periodic samples of the quality of gasoline being sold.

P. V. Rosewarne, H. McD. Chantler and P. B. Seely

The general procedure is to obtain samples from the principal distributing cities in different parts of the country with the assistance of district offices of some government departments. These samples were collected by surveyors, the latter part of July on the river systems of the respective years. For the four years under consideration, the number of samples taken during the summer being

GASOLINE SURVEYS FOR SEVEN SUMMERS

between 1939 and 1946

by

P. V. Rosewarne, H. McD. Chantler and P. B. Seely

-----O-----

A study of the gasoline sold in Canada during the summer has been made annually since 1923 at the Fuel Research Laboratories of the Division of Fuels, Bureau of Mines, and reports from the results obtained have been prepared and published up to, and including 1938(1). The publication of these reports was discontinued during the war although the Laboratories continued to make periodic surveys of the quality of gasoline being sold.

The general practice was to obtain samples from the principal distributing cities in different parts of the country with the assistance of district offices of some government department. For the summer surveys, samples were collected some time during the latter part of July or the first part of August for the respective years. For the four years, 1942 to 1945, a considerable number of samples taken during the summer - summer being understood as the period from May 15 to September 15 in any year - were tested for the Office of the Oil Controller and other government departments. The results of these tests have been included in this report although the samples may not have been taken as close to the first of August as the samples taken in other years. The number of samples taken in the various years has been tabulated for easy reference, as follows:

<u>Year</u>	<u>No. of Samples</u>	<u>No. of Cities</u>
1939	60	9
1940	--	--
1941	92	14
1942	41	--
1943	32	--
1944	61	--
1945	85	--
1946	61	9

It will be noted that no samples are reported for the year 1940 but that a complete coverage for Group 1 gasoline is given for all the other years. Only a partial coverage for Group 2 gasolines is given for these years because there was not a sufficient number of samples obtained in this group to give representative data. The detailed results of the analyses of 432 samples of gasoline sold in Canada

during the summer in the seven years listed above are given in this publication. The support and generous co-operation of the Foods and Drugs Laboratories of the Department of National Health and Welfare and of the Weights and Measures Inspection Service of the Department of Trade and Commerce in the collection of samples is gratefully acknowledged.

Methods of Analysis

The characteristics of the gasoline were tested in each year, according to the latest revision of the methods⁽²⁾ of testing of the American Society for Testing Materials (A.S.T.M.), except as noted below. The distillation range was determined according to A.S.T.M. method D 86⁽²⁾ and was reported on the "per cent recovered" basis. From the results so obtained a weighted index number was calculated after the method advocated by Gruse⁽³⁾, except that the temperatures of the distillation range were expressed in degrees Fahrenheit instead of in degrees Centigrade. By this method, the index number is the sum of the 10 per cent, 20 per cent, 50 per cent, 70 per cent, 90 per cent and end point of the distillation range. The "per cent evaporated" at any temperature is the sum of the "per cent recovered" plus the distillation loss. The temperature of the "per cent evaporated" was determined graphically. The knock ratings of the gasoline are expressed in octane numbers, and were determined by the A.S.T.M. method, D 357-40⁽²⁾. The Reid vapour pressure was determined according to A.S.T.M. method D 323⁽²⁾. The sulphur content was determined according to A.S.T.M. method D 90-34T⁽²⁾, except that a modified apparatus⁽⁴⁾ was used. The gum content was determined by A.S.T.M. method D 381⁽²⁾. The corrosion test was made according to A.S.T.M. method D 130⁽²⁾. The specific gravity was determined by means of the hydrometer at room temperature, according to A.S.T.M. method D 287 and the result calculated to 60°F., according to the National Standard Oil Tables (5). The equivalent degrees A.P.I. was obtained from the above tables. The apparent colour of the gasoline was observed. The tetraethyl lead content was determined according to A.S.T.M. method D 526⁽²⁾, using the volumetric molybdate method.

Results of Laboratory Examination

The results of the laboratory examination of the gasolines tested in the seven summers are shown by cities and by provinces, in Tables 1 to 7. These tables give the A.S.T.M. octane number, distillation characteristics, index No. °F., specific and A.P.I. gravity, Reid vapour pressure, sulphur content, and gum content for all the samples. The tetraethyl lead content of samples for 1946 only is given, and

appropriate average results are shown also. It should be noted that the distillation temperatures are reported on the "per cent recovered" basis for the first six summers, but in summer 1946, the distillation temperatures are reported on the "per cent evaporated" basis.

Table 8 is a summary of the average analyses of the gasoline survey by provinces for summer 1939 and shows the averages of all samples in Group 1, 2, and 3. It also gives the average of all samples tested in that summer. Tables 9 to 14 give similar compilations of the average analyses for the six summers, 1941 through 1946. Again, it should be noted that the distillation temperatures are reported, in the above tables, on the "per cent recovered" basis for the first six summers and on the "per cent evaporated" basis for summer of 1946.

Tables 15 to 21 give the minimum and maximum and average figures for each characteristic of each group of gasoline sold in the seven summers under review.

Table 22 shows the average results obtained by examination of samples of gasoline for the summers of 23 years, from 1923 to 1946 (except 1940), with distillation range reported on the "per cent recovered" basis. The figures for distillation range shown in Table 22 were converted graphically to the "per cent evaporated" basis shown in Table 23.

Table 24 gives the summary of the data of the average of all samples of gasoline in Group 1 and Group 2 for nine summers, 1937 through 1946 (except 1940), with the distillation range calculated graphically to the "per cent evaporated" basis. Figure 1 shows graphically the data given Table 24, except that the gum content is omitted.

A general discussion of the significance of the laboratory tests, together with the relationship between these tests and the actual operation of the fuel in an engine will be found in the report on Gasoline Surveys for 1930 and 1931(6). Intervening changes in the significance of tests on motor fuels were discussed in the Gasoline Surveys for 1935 and 1936(7). For further information on motor fuels, a report (8) entitled "The Significance of Tests of Petroleum Products", which was prepared by A.S.T.M. Committee D-2 of American Society for Testing Materials, the "C.R.C. Handbook" (9), 1946 Edition, compiled by the Coordinating Research Council, Inc., and other reports (10)(11)(12)(13) should be consulted.

During the war from June 28, 1940, to October 1, 1945, the Oil Controller, Department of Munitions and Supply, had jurisdiction over the refining, sale and distribution of all motor gasoline sold in Canada. Orders(14) were issued by the Office of the Oil Controller that permitted only two grades of motor fuel, namely Grade 1 and Grade 2. Specifications

for these graded motor fuels were defined in six orders issued as, Order No. Oil 008A, 008B, 008C, 008D, 008E and 008F. Therefore, all analyses reported in this survey for the four summers, 1942 to 1945, were Grade 1 or Grade 2 gasoline according to the current Oil Controller's Specifications. The Canadian Government Purchasing Standards Committee's Specification (15) for gasoline No. 3-GP-1, was revised at intervals during this period to conform with the orders of the Oil Controller. An abstract of the specifications in these Orders is shown in Appendix A and B.

Although for four summers during the war the gasolines reported in this survey were analyzed to determine whether the sample conformed with the Oil Controller's Specification, or with Specification No. 3-GP-1, the results of analyses are compiled for this survey with a different purpose in view. It is intended as a means whereby information regarding the characteristics of gasoline actually being sold will become available. No effort, therefore, has been made to fit the results into predetermined groups; rather, it was desired that the actual analyses would define as clearly as possible the limits of the different groups of gasoline on the market.

Knock Ratings

The knock rating of the samples tested in the seven summers was determined in a Coordinating Fuel Research Engine, known more briefly as the "C.F.R. Engine". The A.S.T.M. "motor" method, D 357-40(2) was used and the results are expressed in A.S.T.M. motor octane numbers.

According to the knock rating only, the samples tested in summers 1939, 1941 and 1946 fell into three groups, and those tested in summers 1942 through 1945 fell into two groups. The range in octane number of each group was as follows:-

Summer	<u>Group 1</u>	<u>Group 2</u>	<u>Group 3</u>
	<u>Octane No.</u>	<u>Octane No.</u>	<u>Octane No.</u>
1939	75 and above	74 to 65	64 and below
1941	77 and above	76 to 70	64 and below
1942	78 to 75	70 to 65	-
1943	78 to 75	-	-
1944	76 to 74	70 to 66	-
1945	74 to 73	70 to 66	-
1946	77 and above	76 to 70	69 and below

The knock rating of individual samples is given in Tables 1 to 7, and the group in which each sample falls is shown. It will be noted that for summer 1943, no analyses of Group 2 gasolines are reported. This was due to the emergency conditions existing during the war, when the testing of motor

fuels was necessarily limited to essential samples. Therefore, although Group 2 gasolines were sold in Canada during the summer of 1943, the number of Group 2 samples tested by these laboratories was too small for the data to be of value for the purpose of this report, and therefore are not included.

Maximum and Minimum Knock Ratings

The minimum and maximum knock ratings of the samples sold in the seven summers, are shown in Tables 15 to 21. In summer 1939, the range in knock rating of the Group 1 gasolines was from a high of 80 to a low of 75 octane number, and from 80 to 77 octane number in summer 1941. During the four summers, 1942 through 1945, when only graded motor fuel as specified by the Oil Controller was sold in Canada, the range in knock rating of Group 1 gasoline was from a high of 80 to a low of 71 octane number. The orders of the Oil Controller for graded motor fuel were rescinded on August 15, 1945, and in the following summer, 1946, the range in knock rating of the Group 1 gasoline was from a high of 81 to a low of 75 octane number.

For the Group 2 gasoline samples, the range in knock rating was from a high of 73 to a low of 65 octane number in summer 1939, and from 76 to 70 in summer 1941. During the summers 1942 through 1945, the range in knock rating of Group 2 gasoline was from a high of 70 to a low of 65 octane number. After the cancellation of the Oil Controller's orders, the range in knock rating of the Group 2 gasoline was from a high of 76 to a low of 70 octane number in the summer, 1946.

The range in knock rating of Group 3 gasolines was from a high of 64 to a low of 51 octane number in summer 1930 and from 69 to 51 in summer 1941. From 1942 to 1945 no Grade 3 gasoline was sold in Canada. However, in the summer of 1946 three samples of Group 3 gasoline were tested, which had a range of octane number from a high of 62 to a low of 51 octane number. Generally speaking, the major oil companies tend to sell only Group 1 and Group 2 gasolines at their service stations.

Average Knock Rating

The average knock rating of the gasoline sold in Canada in nine summers, 1937 through 1946 (except 1940) are shown in Table 24 and graphically in Figure 1. The results of previous surveys in the summers of 1937 and 1938 are included for comparison. The average knock rating of the samples in Group 1 was 77.6 octane number in summer 1937, 77.8 in summer 1938, 77.4 in summer 1939, 79.0 in summer 1941, 76.9 in summer 1942, 75.7 in summer 1943, 74.8 in summer 1944, 73.5 in summer 1945, and 77.8 in summer 1946.

The average knock rating of the samples in Group 2 was 70.1 octane number in summer 1937, 70.2 in summer 1938, 70.3 in summer 1939, 73.6 in summer 1941, 67.1 in summer 1942, 68.6 in summer 1944, 68.5 in summer 1945, and 73.6 in summer 1946.

The four samples of Group 3 gasoline tested in summer 1939 and the three samples tested in summer 1946 are considered to be insufficient in number to indicate current trends in those years, but are given in this survey for record purposes only. Sixteen samples of Group 3 gasoline tested in summer of 1941 appear to indicate more correctly the characteristics of the Group 3 gasoline sold in that year, and gave an average knock rating of 63.5 octane number.

Changes in Knock Rating

The above results indicate that for three summers, 1937 through 1939, there was very little change in the knock rating of Group 1 or of Group 2 motor fuels sold in Canada. However, by the summer of 1941, the average knock rating of Group 1 gasoline had risen to 79, a difference of 1.5 octane number, while the average knock rating of Group 2 gasoline had risen to 73.6, a difference of 3 octane number. During the next four summers the average knock rating of Group 1 gasoline decreased progressively from 76.9 in the summer of 1942, to 73.5 in the summer of 1945. In the same interval the average knock rating of Group 2 motor fuel remained fairly constant at about 68 octane number. The decrease in knock rating of Group 1 gasoline was due to the shortage of tetraethyl lead. When more tetraethyl lead became available the average knock rating of Group 1 gasoline rose to 77.8 in summer of 1946, a difference of 4.3 octane number, and at the same time, the average knock rating of Group 2 gasoline rose to 73.6, a difference of 5.1 octane number.

The difference between the knock rating of Group 1 and Group 2 motor fuels was 7 octane number in summer 1939 and 4 octane number in summer of 1946.

In the summer of 1941, the average knock rating of Group 3 motor fuels was 57 octane number in the provinces of Manitoba and Saskatchewan and 66 in the provinces of Quebec and Ontario. In the summer of 1946 the knock rating of Group 1 and Group 2 motor fuels sold in the provinces of Saskatchewan and Alberta was about 2 octane number lower than for similar grades of fuel sold in the other provinces.

Tetraethyl Lead Content

Tetraethyl lead is used to improve the knock rating of gasolines and during the war was in short supply as indicated above. Determinations of tetraethyl lead content were made

only on the 1946 summer samples. The tetraethyl lead content of the individual samples is shown in Table 7, and Table 14 gives the average tetraethyl lead content of Group 1 and of Group 2 samples in each province. As shown in Table 21, the maximum tetraethyl lead content of Group 1 gasoline was 3.30 millilitres per Imperial gallon; the minimum was 1.50 millilitres, and the average was 2.45 millilitres. In Group 2, the maximum tetraethyl lead content was 2.06 millilitres per Imperial gallon; the minimum was 0.48 millilitres and the average content was 1.40 millilitres for those samples that contained tetraethyl lead. It should be noted that in the summer of 1946 two samples of Group 2 motor fuel from Ontario did not contain tetraethyl lead.

Volatility

The volatility of the gasoline is indicated by the distillation range temperatures which are given in Tables 1 to 24 and are shown graphically in Figure 1. The distillation temperatures are given on the "per cent recovered" basis in Tables 1 to 6, 8 to 13, 15 to 20, and in Table 22, but they are reported on the "per cent evaporated" basis in Tables 7, 14, 21, 23, 24 and in Figure 1. It is now accepted practice in the petroleum industry to report the distillation range on the "per cent evaporated" basis because these temperatures indicate more correctly the actual volatility of motor fuel as it occurs in engine operation. The average volatility of gasoline sold in Canada during the summer from 1923 to 1946 is given in Table 22 on the "per cent recovered" basis, and the data from this table was converted for purposes of comparison to the "per cent evaporated" basis, shown in Table 23.

When compared with the average volatility of the gasoline sold in summer 1938, it will be noted that the average volatility varied considerably during the seven summers under discussion, with the highest volatility in 1942 and the lowest volatility in 1944. During the war, the production of aviation fuels, synthetic rubber and solvents - used in the manufacture of explosives and war materials - required an increasing proportion of the more volatile constituents of the gasoline fractions produced from the available crude oil. To meet this critical situation in regard to the supply of volatile hydrocarbons from petroleum, the Oil Controller ordered a reduction in the amount of the more volatile constituents used in the production of motor fuels. This necessary action had the direct effect of lowering the volatility of motor fuels sold in Canada during the summer of 1944. As shown in Table 23, there was an increase in the average volatility in summer 1946 as compared with summer 1945 which was due to a drop of approximately 7°F. in the 10%, 20%, 50%, 70%, 90%, and end point in the average distillation range.

Although this survey contains a fairly complete coverage of the Group 1 motor fuels sold in summers 1939 to 1946, it gives

only a partial coverage for Group 2 motor fuels. Samples of Group 2 gasoline were received only from the province of Ontario in 1942 and 1944, and only from the provinces of Ontario and British Columbia in the summer of 1945. A comparison of the volatility characteristics for the three years 1939, 1941 and 1946 of Group 2 motor fuel shows a higher average volatility in the summer of 1946 than in either of the summers 1939 or 1941.

As shown in tables 8 to 14, the gasoline sold in the maritime provinces of Nova Scotia and New Brunswick during the seven summers 1939 to 1945 was usually lower in average volatility than that sold in the other provinces of Canada at the same time.

Vapour Pressure

The Reid vapour pressure for each of the samples tested during the seven summers is shown in Tables 1 to 7. The average vapour pressure of the gasolines sold in the above seven summers was as follows: 8.3 pounds per square inch in 1939; 8.2 pounds in 1941; 9.2 pounds in 1942; 8.1 pounds in 1943; 7.9 pounds in 1944; 7.9 pounds in 1945; and 8.4 pounds in 1946, as shown in Tables 8 to 14 and Table 22. The highest and the lowest vapour pressure respectively, obtained in these seven summers were as follows: 9.7 and 6.2 in 1939, 10.8 and 5.6 in 1941, 12.0 and 7.6 in 1942, 10.4 and 5.7 in 1943, 11.2 and 5.4 in 1944, 11.2 and 5.1 in 1945, and 9.8 and 6.1 in 1946. The number and percentage of the samples of gasoline that had a vapour pressure over 10 pounds in these seven summers were as follows: none in 1939, 4 samples or 4 per cent in 1941, 6 samples or 15 per cent in 1942, 1 sample or 3 per cent in 1943, 2 samples or 3 per cent in 1944, 3 samples or 4 per cent in 1945 and none in 1946.

In the summer, from 1937 to 1939 there was a definite trend towards higher vapour pressures and generally speaking, more uniform vapour pressures for the gasolines being sold. This trend in the vapour pressure characteristics of gasoline is again noticeable in summer 1946.

Correlation of Vapour Pressure and Volatility

The change in average vapour pressure follows fairly closely the change in the average temperature of the 10 per cent evaporated point in the distillation range. Usually the lower the vapour pressure the higher is the temperature of the 10 per cent evaporated point. As shown in Table 23, the average 10 per cent evaporated point, for the seven summaries, was 142° F. in 1939; 143° F. in 1941; 135° F. in 1942; 140° F. in 1943, 142° F. in 1944; 144° F. in 1945; and 137° F. in 1946. As indicated by the 7.9 pounds average vapour pressure and the 143° F. average temperature of the 10 per cent evaporated point, motor fuels with poor starting characteristics (10) were of necessity sold in Canada during the summers of 1944 and 1945.

Sulphur

Sulphur determinations were made on the gasoline samples received in the six summers, 1941 through 1946, but the sulphur content of the samples received in the summer of 1939 was not determined. The average sulphur content of the gasolines tested in the above six summers was as follows: 0.06 per cent in 1941; 0.05 per cent in 1942; 0.08 per cent in 1943; 0.06 per cent in 1944; 0.07 per cent in 1945 and 0.07 per cent in 1946. Thirty-eight samples or 10.2 per cent of the 371 samples tested in these six summers had a sulphur content exceeding 0.10 per cent. The number and yearly percentage of the samples that exceeded a sulphur content of 0.10 per cent was as follows: 6(6.5%) in 1941; 2(4.9%) in 1942; 8(25.8%) in 1943; 2(3.3%) in 1944; 8(9.4%) in 1945; and 12(19.7%) in 1946. Only 7 samples or 1.9 per cent of the 371 samples tested in the six summers, 1941 through 1946, had a sulphur content exceeding 0.15 per cent. One sample of motor fuel received from the province of Ontario in the summer of 1941 had a sulphur content of 0.16 per cent; two samples received from the province of Quebec in summer 1942 had sulphur contents of 0.17 and 0.16 per cent respectively; and four samples received from the province of British Columbia in 1945 had sulphur contents of 0.44, 0.35, 0.29 and 0.25 per cent respectively.

As shown in Table 14, in the summer of 1946 the motor fuels sold in the maritime provinces of Nova Scotia and New Brunswick had a higher average sulphur content than the motor fuels sold in the other provinces of Canada.

Gum

The gum content of the gasoline was determined only on the samples examined in the last four summers, 1943 through 1946. The gum content for each sample examined in the above four summers is shown in Tables 4 to 7. As noted in Tables 11 to 14, the average gum content of all the samples tested in summer 1943 was 6 milligrams per 100 millilitres of gasoline; in summer 1944 was 4 milligrams; in summer 1945 was 4 milligrams, and in summer 1946 was 4 milligrams. It is now generally accepted (15) that not over 7 milligrams of gum should be present in 100 millilitres of motor fuel. The percentage of the samples, that exceeded the above accepted limit for gum, was 28 per cent in summer 1943, 10 per cent in summer 1944, 10 per cent in summer 1945 and 13 per cent in summer 1946. As shown in Tables 18 to 21, the maximum gum content of a sample was 24 milligrams in summer 1943,

14 milligrams in summer 1944, 21 milligrams in summer 1945 and 18 milligrams per 100 millilitres in summer 1946. In summer 1946, 8 samples of gasoline contained a small amount of oil, which was presumably added as a "top cylinder lubricant". Five of these eight samples were motor fuels received from the cities of Calgary, Alberta, and Vancouver, B.C. and contained from 10 to 20 milligrams of oil per 100 millilitres of motor fuel.

Gravity

The specific gravity at 60°F. and gravity in degrees A.P.I. at 60°F. for each sample tested in summers, 1939 through 1946 are shown in Tables 1 to 7. As indicated in Tables 15 to 21, the overall variation in specific gravity of the gasolines examined during these seven summers was from 0.703 to 0.764 or from 69.8 to 53.7 degrees A.P.I. This is equivalent to a variation in weight of 7.03 pounds to 7.64 pounds per Imperial gallon. The average specific gravity for all the samples examined in summer 1939 was 0.740 or 59.7 degrees A.P.I.; in summer 1941 was 0.741 or 59.5 degrees A.P.I.; in summer 1942 was 0.733 or 61.5 degrees A.P.I.; in summer 1943 was 0.741 or 59.5 degrees A.P.I.; in summer 1944 was 0.743 or 58.9 degrees A.P.I.; in summer 1945 was 0.740 or 59.7 degrees A.P.I.; and in summer 1946 was 0.737 or 60.5 degrees A.P.I., as shown in Table 22. In other words, the average specific gravity of the motor fuels varied from a low of 0.733 in summer 1942 to a high of 0.743 in summer 1944, which corresponds to a variation in degrees A.P.I. from 61.5 to 58.9. This is equivalent to a variation in weight of 7.33 pounds to 7.43 pounds per Imperial gallon for summer gasoline.

Corrosion

The corrosion test for motor fuels is made by immersing a strip of polished copper for three hours in a sample of the gasoline heated to 122°F. according to A.S.T.M. method D 130-30(2) and observing the tarnish, or corrosion, that takes place. The copper strip should not show more than "extremely slight discolouration". The corrosion test was made on all of the 432 samples tested in the seven summers 1939 through 1946; but in order to conserve space was not reported in any of the tables 1 to 24. None of the 432 samples of gasoline gave a positive test for corrosion according to the above procedure.

Colour

The apparent colour of the gasoline was observed in all samples tested in the seven summers 1939 through 1946, but has not been reported in any of the Tables 1 to 24. In summer 1939,

100 per cent of the Group 1 gasolines, 88 per cent of the Group 2 gasolines, and none of the Group 3 gasolines were artificially coloured. In summer 1941, 100 per cent of the samples of gasoline in Group 1 and 2, and 31 per cent of the Group 3 gasolines were artificially coloured. In the five summers 1941 through 1946, all of the samples of gasoline in Group 1 and Group 2 were artificially coloured. None of the Group 3 gasolines examined in summer 1946 were artificially coloured. It was observed that during these seven summers, the majority of Group 1 gasolines were dyed red and since the summer of 1942, the majority of the samples in Group 2 were dyed yellow or green. The general tendency in the petroleum industry is to colour only Group 1 and Group 2 gasolines and to leave colourless or "white", the Group 3 gasolines, which are usually termed "Third Grade".

Summary and Conclusions

This gasoline survey comprises the analyses of 432 samples of motor fuel received by the Fuel Research Laboratories during the seven summers, 1939 through 1946. No survey was made in summer 1940. In 1939, 1941, and 1946, samples were collected on behalf of the Bureau of Mines, and in the intervening years samples were tested for the Office of the Oil Controller and other government departments. The term, summer, is taken as the period from May 15 to September 15 in any year. Sixty samples were collected from 9 cities in 1939; 92 samples were collected from 14 cities in 1941; 41 samples were tested in 1942; 32 samples in 1943; 61 samples in 1944; 85 in 1945; and 61 samples were collected from 9 cities in 1946.

As all of the above samples were collected from eight provinces, namely Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, Alberta and British Columbia, they may be accepted as representative of the motor fuels sold in Canada during these seven summers. For convenience and easy reference, summaries of the data obtained are tabulated and a comparison of gasoline characteristics is shown graphically.

Group 1, Group 2, and Group 3 gasolines were tested in the three summers 1939, 1941 and 1946. In summers 1942 through 1946, only Group 1 and Group 2 gasolines were tested, but this report contains only a partial coverage of the Group 2 gasolines. During the war, Group 1 gasoline was known as "Oil Controller's Grade 1" or "Premium", and Group 2 gasoline was known as "Oil Controller's Grade 2" or "Regular". These three groups differ principally in knock rating.

The average knock rating by A.S.T.M. motor method of Group 1 gasolines sold in the seven summers was as follows: 77.4 octane number in summer 1939; 79.0 in summer 1941; 76.9 in summer 1942; 75.7 in summer 1943; 74.8 in summer 1944; 73.5 in summer 1945; and 77.8 in summer 1946.

The average knock rating of Group 2 gasolines sold in Canada in six summers was as follows: 70.3 octane number in summer 1939; 73.6 in summer 1941; 67.1 in summer 1942; (No report available for summer 1943); 68.6 in summer 1944; 68.5 in summer 1945; and 73.6 in summer 1946.

The average knock rating of the Group 3 gasolines sold in summer 1941 was 63.5 octane number.

The definite trend to lower knock ratings for the Group 1 and Group 2 motor fuels sold in Canada from summer 1942 to summer 1945 was due principally to the acute world shortage of tetraethyl lead during the war. Orders of the Oil Controller specified the knock ratings that were permitted during this period. Abstracts of the specifications of the Office of the Oil Controller for graded motor fuel are attached as appendices to this report.

The average tetraethyl lead content of the gasolines sold in Canada in summer 1946 was 2.45 millilitres per Imperial gallon for the Group 1 motor fuels and 1.40 millilitres per Imperial gallon for the Group 2 motor fuels.

The average volatility of motor fuels sold in Canada varied considerably during the seven summers 1939 through 1946, with the highest volatility in 1942 and the lowest volatility in 1944. Immediately after the war, in summer 1946, the average volatility of the gasoline rose sharply so that it was greater than in summer 1945. The gasoline sold in the eastern maritime provinces during the seven summers, 1939 through 1946, was usually lower in volatility than in the other provinces of Canada. This lower volatility in the eastern maritime provinces was due mainly to the type of crude oil received at the refineries, and to the necessity of producing greatly increased quantities of fuel oil in that area during the war years.

The average Reid vapour pressure of the motor fuels sold in the seven summers was as follows: 8.3 pounds per square inch in 1939; 8.2 pounds in 1941; 9.2 pounds in 1942; 8.1 pounds in 1943; 7.9 pounds in 1944 and 1945; and 8.4 pounds in 1946. 4 samples of gasoline in 1941, 6 samples in 1942, 1 sample in 1943, 2 samples in 1944 and 3 samples in 1945 had a Reid vapour pressure over 10 pounds. Motor fuels with poor starting qualities were of necessity sold in Canada in the summers of 1944 and 1945.

The average sulphur content of the gasolines sold in Canada in six summers was as follows: 0.06 per cent in summer 1941; 0.05 per cent in 1942; 0.08 per cent in 1943; 0.06 per cent in 1944; and 0.07 per cent in the next two summers 1945 through 1946. One sample sold in province of Ontario in summer 1941, 2 samples in province of Quebec in summer 1942 and 4 samples sold in province of British Columbia in summer 1945

had sulphur contents exceeding 0.15 per cent. The gasoline sold in the eastern maritime provinces in summer 1946 had a higher average sulphur content than the gasoline sold in the other provinces of Canada.

The average gum content of all the gasoline samples tested in summer 1943 was 6 milligrams per 100 millilitres of motor fuel and it was 4 milligrams in the next three summers 1944 through 1946. Twenty eight per cent of the samples in summer 1943, 10 per cent in the next two summers 1944 through 1945, and 13 per cent in summer 1946, exceeded the usually accepted limit of 7 milligrams of gum per 100 millilitres of motor fuel.

The average specific gravity of the gasolines varied from a low of 0.733 in summer 1942 to a high of 0.743 in summer 1944, which corresponds to a variation in degrees A.P.I. from 61.5 to 58.9. The overall variation in specific gravity of the gasolines sold during the seven summers was from 0.703 to 0.764 or from 69.8 to 53.7 degrees A.P.I.

None of the samples tested in the seven summers gave a positive test for corrosion with a copper strip.

Commencing with summer 1941, all of the samples of Group 1 and Group 2 gasolines, tested in the six summers, 1941 through 1946, were artificially coloured. The majority of the Group 1 gasolines were dyed red and the majority of the Group 2 gasolines were dyed yellow or green, and the Group 3 gasolines were usually colourless or "white".

*milligrams per 100 millilitres.

^aper Imperial gallon, millilitres.

(1)Also contains 20 mgs. oil.

(4)Also contains 10 mgs. oil.

(2)Also contains 17 mgs. oil.

(5)Also contains 11 mgs. oil.

(3)Also contains 19 mgs. oil.

(6)Placed in Group I for Alberta only.
