Introduction

A combined magnetic and seismic observatory was established at Mould Bay, Prince Patrick Island, N.W.T., in the summer of 1961 by the Observatories Branch of the Department of Mines and Technical Surveys (now Earth Physics Branch, Department of Energy, Mines and Resources).

A history of the observatory with pertinent details on observatory building, equipment and procedures was given in "Record of Observations at Mould Bay Observatory 1967" by A.E. Evans.

Magnetic equipment

Photographic variometers. A set of three-component standard-run Ruska variometers record the X (north), Y(east), and Z(vertical) components of the earth's magnetic field. The time scale of the Ruska magnetograms is 20 mm/hr.

Observed and adopted scale values for the Ruska variometers for 1969 are listed with the adopted baselines.

Thermostatically controlled electric heaters maintain the temperature in the variometer room constant to within $\pm 1^\circ\text{C}$. The sensitivity of the Ruska temperature trace is $1.4^\circ\text{C}/\text{mm}$. Temperature coefficients determined in February 1969 were found to be negligible in X, $-1.6\gamma^\circ\text{C}$ in Y and $+4.1\gamma^\circ\text{C}$ in Z. Sensitivity of the temperature trace is $1.3^\circ\text{C}/\text{mm}$. Temperature corrections were normally not applied to baseline and mean hourly values, except for periods of power failure when temperature changes

occurred. Appended to this section is a complete report by W. Piche on the procedure used to find temperature coefficients of the variometers.

Parallax corrections to be added to the time read on the magnetogram traces were determined in November 1969, and were found to be -0.5 minute in all elements.

Standby variometer and storm recorder. Continuous traces of X, Y and Z on a strip-chart recorder were provided by a three-component electrical magnetometer in 1969. Full scale chart sensitivity is 1,000 gammas normally with automatic switching to half sensitivity at times of large magnetic disturbances. The chart is operated at 20 mm/hr. Chart values were used to interpolate for missing intervals on the Ruska magnetograms. The chart also provides a continuous visual indicator of magnetic field conditions.

Absolute instruments. A proton precession magnetometer is the primary standard of total intensity (F). A portable electrical magnetometer of the saturable core type is used for the determination of declination (D) and inclination (I).

Determinations of the temperature coefficients of the Ruska variometers

On January 29, 1969 and February 10, 1969, sets of observations were taken to determine the temperature sensitivity of the Ruska variometers. Temperature readings at the reference magnetometer (standby magnetometer) showed some variation during the period of observations and accordingly, on March 4, 1969,

a set of observations were taken to determine the temperature sensitivity of the standby magnetometer. From this, appropriate corrections were applied to the previous observations in an effort to obtain more accurate temperature sensitivity determinations for the variometers.

Procedure. On January 29 it was apparent that a period of quiet magnetic conditions and fairly low outside temperatures would prevail. At 0200 U.T. the Ruska variometer room heaters were turned off and the room was allowed to cool through natural heat loss. Heat was maintained in the standby variometer room. Temperature readings of the Ruska Z variometer and the standby variometer head were taken at regular intervals throughout the cooling. At 0900 U.T. the rate of cooling had decreased to a point which made further cooling impractical. At this time heat was restored to the Ruska variometer room and temperature readings continued as before until the variometer room temperature had returned almost to normal.

On February 10, when conditions were again suitable, the experiment was repeated. Heaters in the Ruska variometer room were turned off at 0300 U.T. and temperature readings were taken at regular intervals throughout the period of cooling. At 1000 U.T. the heaters in the Ruska variometer room were turned on and temperature readings were continued until the temperature returned to normal.

At a later date the two sets of records were analyzed. Each component of the Ruska and standby variometer magnetograms was scaled in detail. Quarter-hourly means were obtained for each of the Ruska variometer traces to the nearest 0.6γ variation from respective baselines and the variation of the standby variometer traces to the nearest 1γ from arbitrarily selected lines. An arbitrary constant was

*Assuming the position of the geomagnetic pole is 78.3°N , 69.0°W (Finch and Leaton, 1957).

subtracted from each of the scaled values from the Ruska variometers. This served to keep the values small and to reduce the effect of minor variations in scale values. Suitable selection of reference lines made this procedure unnecessary for the flux-gate traces.

The quarter-hourly means were then averaged and tabulated as half-hourly means. These values were converted to gammas using previously determined scale values. The half-hourly means for each standby variometer component were subtracted from the corresponding half-hourly means for each Ruska component. A "constant" value or "zero reference" was obtained for the period during which both sets of instruments were operating at normal temperatures prior to the cooling procedures. Deviation from this constant value during cooling of the Ruska variometer room represented the temperature sensitivity of the respective components. The temperature sensitivity of each component was then calculated by plotting the deviations against the change in temperature and fitting a line through the data points by the least squares method.

Observations. Observed data and fitted lines for the Ruska temperature calibration performed on February 10, 1969 are shown in Figure 1. Observed data and fitted lines for the standby variometer temperature calibration are shown in Figure 2.

Conclusions. On the basis of the temperature calibration with the least scatter in the results the temperature sensitivities adopted for the Ruska variometers are as follows:

X negligible

Y -1.6 ± 4 gammas/degree centigrade

Z 4.1 ± 4 gammas/degree centigrade

The horizontal components of the standby variometers showed a negligible temperature coefficient for normal variation in temperature. However the Z component showed a large dependence of 5.4 ± 2.7 gammas/degree centigrade. It is interesting to note that a parabolic curve of the form

$$Z = 0.75\Delta T - 0.60(\Delta T)^2 + Z_0,$$

ΔT = temperature change in degrees centigrade

fits the observed data points within the limits of the experimental error (± 1 gamma).

Absolute observations and baseline values

Absolute determinations of D, I and F were made on the average five times a month during magnetically quiet periods.

The method used for calculation of the Ruska X, Y and Z values from absolute measurements of D, I and F was discussed in detail in the 1967 report for Mould Bay.

The baselines and scale values for X, Y and Z for 1969 are in the accompanying tables.

Magnetic reductions

Details of reduction of the magnetic data were given in the 1967 report for Mould Bay.

Microfilm copies of the standard-run photographic magnetograms with provisional baseline and scale values were supplied to World Data Centre A, Washington, on a monthly basis.

The five local quiet days for each month, selected on the basis of the R indices are listed below. Local quiet days which do not appear also in the list of 10 international quiet days are underlined. The five international quiet and disturbed days are labelled Q and D respectively in Tables 1-36.
