# GRAVITY IN WESTERN CANADA

## INTRODUCTION

This publication contains the results of all gravity stations that have so far been established in Western Canada. The determinations were made with the standard half-seconds pendulum apparatus of the Observatory. At every station the pendulum case was set up either on a concrete basement floor or a concrete block specially erected for the purpose. Flexure was measured with an interferometer. At the thirteen stations whose numbers are given as 31 to 43 the rates of the chronometers were determined directly by telegraphic connection with the Observatory clock. The rates at all the remaining stations, with the exception of four, were obtained by comparison, by the method of coincidences by extinction, with a chronometer set to gain, in most cases, about one second in fifty seconds on the mean time wireless signals from Annapolis. At the end of the season of 1925 when Annapolis was not sending it became necessary for the four stations mentioned to make use of the signals from either Arlington or WQL. For the last three years it has been the practice for the pendulum observer to make his own time comparisons with a small receiving set that is built for the purpose by the Observatory.

The more important results of the work in this part of the country are summarized in the tables appearing throughout the report and are in part shown graphically on the two accompanying maps. Descriptions of the stations and tables giving information of a more or less detailed nature, and to which no particular reference is required, appear at the end of the publication. Similar information for those stations not appearing in the latter tables has been given in previous publications of the Observatory.

In certain cases the name and other information corresponding to a certain station number may be required. In order to satisfy this requirement the stations are listed in their numerical order in Table I. This table also gives the gravity anomaly, the observer and the year in which the station was established.

## GRAVITY ANOMALIES

As the gravity anomalies (the differences between the observed and computed values) form a very important part of the results of a gravity investigation, the computation of theoretical values for each station becomes also a matter of considerable importance. The observed values are, of course, obtained from the pendulum observations. The computed values given in this publication are values which are obtained on the assumption of isostasy. Corrections have been made for the gravitational effect at each station of all the topography on the earth's surface, and the compensating effect due to diminished density beneath the continents and increased density under the oceans has also been taken into account. The compensation is assumed to be complete and distributed uniformly down to a depth of 113.7 kilometres. In making the computation a formula for gravity at sea-level is first assumed. In this case, Bowie's

formula,  $\gamma_0 = 978.039 (1 + .005294 \sin^2 \phi - .000007 \sin^2 2\phi)$ , derived from over 200 stations in different parts of the world, has been taken. To change to the position of the station this is corrected for the diminished attraction due to increased distance from the centre of the earth and to this result there is finally applied the correction for topography and compensation to which reference has already been made. The results are given in Table II, in which the stations are separated into groups according to the provinces in which they are situated. The first five columns give the number, name, longitude, latitude and altitude of the station. The sixth column gives the value of  $g$  at sea-level ( $\gamma_0$ ) for the latitude ( $\phi$ ) of the station. The corrections for altitude and for topography and compensation are given in the next two columns. Columns 9 and 10 contain the computed and observed values. The gravity anomalies are given in the last column, and they are obtained by subtracting the computed values from the observed values. A positive anomaly indicates an excess of gravity and is obtained when the observed value is greater than the computed value. An anomaly of .001 dyne (or cm. per sec. per sec.), about one-millionth part of gravity, is equivalent to the effect that would be produced at the station by a layer of rock 30 feet thick and of density 2.7.

It is obvious that a gravity anomaly may be due to one cause or a combination of a number of causes. To produce an anomaly of any magnitude, however, the number of the more important causes is limited. With sufficient computation it may in certain cases be possible to form a fairly definite estimate of the chief cause or causes of the anomaly.

One of the possible causes of a gravity anomaly is the existence of abnormal rock densities in the vicinity of the station. In computing the effect of topography for the station the normal rock density is taken as 2.67. If the density of the rock in the vicinity of the station is different from this and if the excess or deficiency of material is uncompensated, provided there are no other compensating disturbances, a gravity anomaly is bound to result. If the excess or deficiency along with the original mass is completely compensated it turns out, rather paradoxically, that an anomaly will be produced if the horizontal extent of the abnormal density is not too great. This is a fact that was first pointed out by Bowie. A few figures illustrating this may be of some interest. Suppose at Elbow (No. 80) where gravity is practically normal, we were to replace the existing rock, whose density is taken for the present to be 2.67, by heavier rock of density 2.94 (10 per cent greater) extending to a depth of 10,000 feet. If the deposit extended out in every direction to a distance of one mile from the station the anomaly would be .012. The maximum anomaly .026 would be reached for a distance of five miles. For 100 miles the anomaly would decrease to .010 and for 750 miles would be only .002. If the excess of matter were uncompensated the anomaly for 5 miles would be .028, for 100 miles .034 and for 750 miles .037. If in addition part or all of the original mass were uncompensated the anomalies would be still larger.

It is characteristic of large anomalies that they do not persist over large areas. This is well illustrated by the variation of the anomalies over the Puget Sound district in the United States, to which attention has been directed by Bowie and others. Considerable interest has been added to this region by the recent work on Vancouver island. In a distance of 20 miles across the strait of Juan de Fuca there is a change

from a negative anomaly of  $-0.008$  at Port Angeles to the largest known anomaly in Canada,  $+0.054$  at Victoria. This is also one of the largest positive anomalies yet discovered on the whole continent. Inside a distance of approximately 75 miles we go from the largest negative anomaly on the continent at Seattle to the large positive anomaly at Victoria. The chief cause of the large anomalies in the United States has been attributed by Bowie to local densities. It is certain that this is at least partly the cause of the anomaly at Victoria. A determination of the densities of several samples of the rock exposure (Gonzales hill) on which the station is situated, showed that none of them had a density less than  $2.75$  while the average was  $2.81$ . This is considerably in excess of the assumed normal density of  $2.67$  and no doubt there is still heavier rock near the station, as the geological reports of the Victoria district give analyses of the rock in this vicinity all with densities considerably higher than those already mentioned. At Ocean Falls again what seemed to be a fairly representative sample of rock in the vicinity of the station had also a density of  $2.81$ . The anomaly here is small but positive. In Masset inlet a sample taken from an exposure which seemed fairly typical, when weighed, was found to have a density of  $2.67$ , the normal value. The anomaly at Masset is slightly negative. At Phoenix we have a fairly large positive anomaly. The gravity station is located on a copper mine which is underlain with grano-diorite, the average density of which is also in excess of the normal value  $2.67$ .

The collecting of rocks in the vicinity of the stations was begun only towards the end of the field season of 1926. The limited number of densities that have been mentioned represent the values for all rock samples that have so far been collected. When time permits for further computation and investigation it is proposed to give further attention to the consideration of the individual anomalies. While it is certain that anomalies may not always be due to abnormal densities, there is sufficient evidence to show that for some of our Canadian stations there is a relation between the anomalies and the local densities. The value of the observations in revealing abnormal densities that may not otherwise be apparent is at least worthy of consideration.

#### RELATION BETWEEN THE ANOMALIES AND THE GEOLOGICAL FORMATIONS

Connected, quite possibly, with the relations that have just been mentioned are the relations that apparently exist between the anomalies and certain of the geological formations. In the accompanying table (Table III), giving the anomalies, the stations are grouped according to the geological formations upon which they are situated. The classification has been made from the geological map of Canada, dated 1924. A geological map, with the stations and their anomalies marked upon it, accompanies this report.

An examination of the summary of Table III indicates quite definite relations between the anomalies and both the Mesozoic and the Tertiary. Nearly all the Mesozoic stations have positive anomalies, while the Tertiary stations with the exception of Estevan are all negative. In the case of the igneous of the Mesozoic a plausible explanation of the anomalies is the existence in this formation of heavy igneous rocks. If the anomalies of the Cretaceous are due to abnormal densities they must lie beneath the sedimentary formation as the rocks of the formation are supposed to be lighter than

normal. In this case the contour lines on the gravity map would give some idea of the shape of the underlying formation. The anomalies on the Tertiary could be explained by the lower densities which the rocks of this formation are known to have.

The relations between gravity anomalies and the two geological formations—the Cretaceous and the Tertiary—have already been found by Bowie to exist for gravity stations in the United States.

There are no very definite relations between the other formations and their anomalies. It is quite possible that as the survey is extended into other parts of the country relations between the results and some of the other formations may be found.

#### ISOSTASY IN WESTERN CANADA

Judging from the anomalies it may be inferred that the greater portion, if not all, of that part of Western Canada covered by the observations, is in isostatic equilibrium or in a condition closely approximating it. Stations with large anomalies are not very numerous and, as already indicated, it is possible that these may be explained at least in part, if not wholly, by conditions which are local and are not a violation of isostasy. The anomalies on the southern part of Vancouver island may possibly be explained by the local densities. For example the anomaly at Victoria could be entirely accounted for by a compensated block of density 2.94, and 5 miles in radius, extending to a depth of 25,000 feet. There may be some doubt about Saskatchewan and the southern part of Manitoba. This area of comparatively large positive anomalies is not confined to Canada but runs across the border into the United States and reaches still larger values in the western part of South Dakota. If the anomalies in this region cannot be explained by the density and form of the underlying formation they may possibly indicate a lack of compensation.

It is also certain that there is no other known method of computing gravity, which does not involve the assumption of isostasy, that will give values of gravity that agree with the actual observed results. For the purpose of illustrating this fact anomalies obtained by different methods of computing gravity are given in Table IV for 20 stations in the mountainous part of the country. The Free Air and Bouguer methods are two old and well known methods of computing gravity. It is also well known that generally they give erroneous values. The interesting comparison is between the isostatic and rigid crust anomalies. The rigid crust anomalies are obtained by leaving out of consideration the correction for compensation but by taking into account the entire topography of the earth's surface.

#### DEPTH OF COMPENSATION

Two determinations of the depth at which isostatic equilibrium is reached have been made. One of these, by the method of least squares, gives for nine stations in the Mackenzie river basin a depth of 91 kilometres with a probable error of 29 kilometres. A more accurate determination has been obtained from the results of the twenty stations, already referred to, in the Cordilleran region. The result of this determination is shown graphically in fig. 1 by a method first used by Bowie. The gravity anomalies for a number of depths were computed from tables published by the U. S. Coast and Geodetic Survey. According to the theory of probabilities the most probable depth of compensa-

tion is that for which the sum of the squares of the residual gravity anomalies is a minimum—the lowest point on the curve of fig. 1. The plotted points in the figure, indicated by the circles, are the results of the computations. The curve is obtained by joining these points. Evidently, the most probable depth of compensation for the twenty stations is between 85.3 and 113.7 kilometres, possibly slightly less than 100 kilometres.

*Figure 1. Graphical determination of the depth of compensation from 20 stations in the southern portion of the Canadian Cordillera.*

## REGIONAL TENDENCIES OF THE ANOMALIES ILLUSTRATED BY THE GRAVITY MAP

The positions of the gravity stations with their numbers and their anomalies for a depth of compensation of 113.7 kilometres have been plotted on one of the official maps of Canada. A copy of this map will be found at the end of this publication. Regions of positive anomalies are shown in green, while negative areas are shown in yellow. Lines are drawn through places where the anomalies are the same and have certain values which are indicated on the map. The position of these lines is naturally not so certain in areas where the stations are not so numerous. The information for stations south of the international boundary, designated by the letter 'S', has been taken from the special publications of the U.S. Coast and Geodetic Survey.

The tendencies, as regards sign, of the anomalies are quite interesting. By consulting both the maps it will be seen that we start with a region of negative anomalies over the Paleozoic formation in Manitoba. Coming next to the wide Cretaceous formation which extends out to the Rockies we find that nearly all the anomalies are positive. Next we come to the Tertiary formation along the mountains in Alberta and the only two stations on it, Calgary and Red Deer, give negative anomalies of about the same magnitude. The most mountainous part of British Columbia is characterized by negative anomalies. These could be explained by the great depth of sedimentary and therefore lighter rocks or by the fact that the depth of compensation, 113.7 km., is greater than the indicated depth for this area. It is also possible that the assumed depth of compensation (113.7 km.) may differ considerably from the actual depth for the prairies, but it may be mentioned that for such extensively level regions, and for places where the compensation correction is small, a change in the depth of compensation does not so materially affect the anomaly. Although there are not sufficient stations on either formation to definitely establish the state of affairs, it appears from those that exist that the Nelson and Coast range batholiths are regions of positive anomalies.

Gravity is less than normal at the northern end of the Queen Charlotte islands. The southern part of Vancouver island is quite definitely a region of positive anomalies and Victoria has the largest anomaly of any of the 69 stations. The Edmonton district and the region north of it are remarkably normal in so far as gravity is concerned. All the way down the Mackenzie this state of affairs exists till we reach Good Hope, when we come to a region where the anomalies are getting larger and have changed to positive values. On the prairies the largest anomalies are at Manitou, Estevan and Saskatoon and they are all positive.

## ACCURACY OF THE OBSERVATIONS AND REDUCTIONS

An estimate of the accuracy of the observations may be obtained by examination of Tables V, VI and VII. Table V gives the periods of the pendulums resulting from the various standardizations at Ottawa and also the adopted values for each season. The periods of the pendulums at the field stations and the deduced values of  $g$  are given in Table VI. Table VII gives the pendulum observations and the reductions giving the times of vibration from these observations.

If the probable errors of the field observations are determined from Table VI it will be found that there are 15 stations with a probable error of .000 dyne, 39 with .001 dyne, 11 with .002 dyne and 2 with .003 dyne. The two stations at which only one

pendulum was used are not included in this list. The results are no doubt more in error than these figures would indicate. If we add to them the probable errors in the determinations of the mean periods of the pendulums obtained from the spring and fall standardizations at Ottawa it will be found that this sum is zero for 11 stations, .001 for 15 stations, .002 for 24 stations, .003 for 6 stations, .004 for 10 stations and .005 for 1 station. The average is .002. During 1924 and 1925 when most (40) of the stations were established the pendulums remained quite steady during each season. During the season of 1915 also the behaviour of two of the pendulums was quite satisfactory. The stations with the largest uncertainties in the observed values are the 9 in the Mackenzie river basin and 8 established along the Pacific coast in 1926. The probable error in the determination of these stations is estimated to be about .004 to .005 dyne.

The corrections for topography and compensation for separate zones are given in Table VIII. Similar tables for the Mackenzie river stations are given in these Publications, Vol. VIII, No. 6. The reductions for all the stations have been made by the writer. Eleven of the stations were also reduced by Mr. McDiarmid. As no record of the corrections for separate zones was kept and as a number of new maps have been published since the earlier reductions were made, it was considered desirable to repeat the work. For the Prairies the writer's values for the corrections are, on an average, .010 dyne less than those previously obtained. In the mountains the differences are somewhat larger. Taking into consideration the nature of the topography there is only one station where a large difference exists between the two reductions. This is at Revelstoke. The mapping around this station is rather incomplete but in spite of this the writer is inclined to think that the previously published value for Revelstoke was too small. Owing to the fact that the necessary maps are not available, at the present time, no attempt has been made to make the reduction for North Bend.

With the exception of the stations in the mountains, most of which are in the interior of British Columbia, the probable error of the reductions is estimated at less than .005 dyne. The stations in the mountains, especially those in the more mountainous parts, may be in error by as much as .010 dyne.

Directly affecting the computed values are the elevations of the stations. An error of 11 feet in elevation introduces an error of .001 dyne in the computed value of  $g$ . There is only one station (Liard River) for which the assigned elevation may be very much in error. It might be as much as 100 to 150 feet higher than has been estimated. The elevations of Resolution and the four stations on Mackenzie river may be from 20 to 50 feet in error. With the possible exceptions of Paradise Mine and Barkerville the elevations of all the remaining stations have been determined by methods which should give results that are correct to within a few feet. In many cases they have been determined precisely from accurate elevations (rail levels) or bench-marks of the Geodetic Survey. The elevations to which stations are referred are given in the descriptions of the stations.

## DISTRIBUTION OF THE COMPENSATION

No computations have so far been made by the writer for possible distributions of compensation other than for the uniform distribution upon which the Hayford and Bowie reduction tables are based. There is reason for believing, however, that on the average not very different results would be obtained by any other simple assumption that is likely to represent the actual facts. In fact Heiskanen\* has shown from the results of observations, and Jeffreys\*\* theoretically, that by merely a change in the depth of compensation very much the same anomalies are obtained from quite a different (Airy's) distribution of the compensation.

## DESCRIPTIONS OF STATIONS

No. 52, Dauphin, Man. (1924).—The pendulum was set up in the northeasterly corner of the furnace room in the basement of St. Paul's church at the SE. corner of 1st St. SW. and 4th Avenue SW. The point is 93 feet in an easterly direction along 4th Avenue SW and 33 feet in a southerly direction, parallel to 1st Street SW., from the street corner mentioned. It was 4 feet 4 inches below the level of the rail in front of the C.N.R. station.

No. 53, Swan River, Man. (1924).—The pendulum was set up in the northeast corner of the basement of Mr. Agnew's drug store (lot 19 town of Swan River). By scaling from the plan of the town of Swan River the point was found to be 706 feet south and 1,380 feet east of the quarter-section corner on the east boundary of sec. 20, tp. 36, rge. 27, W. Pr. mer. It is 8 feet below the level of the rail in front of the C.N.R. station.

No. 54, The Pas, Man. (1924).—The pendulum was set up in the east end of the room on the south side of the basement of The Pas school. By scaling from the plan of The Pas the point was found to be 666 feet south, and 5,415 feet west of the I.P.M. near (20 chains south) the NW. cor., sec. 11, tp. 56, rge. 26, W. Pr. mer. It is 8 feet 8 inches below the level of the Topographical Survey bench-mark on the southerly abutment of the railway bridge across Saskatchewan river.

No. 55, Prince Albert, Sask. (1924).—The pendulum was set up in the west end of sample room No. 6 on the south side of the basement of the Empress hotel at the corner of 11th St. and 1st Ave. W. By scaling from the plan of the city, the point was found to be 3,369 feet south and 35 feet east of the quarter-section corner on the east boundary of sec. 9, tp. 49, rge. 26, W. 2nd mer. It is 15 feet below the elevation of the rail in front of the C.N.R. station.

No. 56, Saskatoon, Sask. (1924).—The pendulum was set up in the southwest corner of the Physics laboratory in the southwest corner of the basement of the Physics building. The point is 782 feet north and 2,375 feet west of the southeast corner of sec. 34, tp. 36, rge. 5, W. 3rd mer., and its elevation, referred to the levels of the Geodetic Survey, is 1,629 feet. The information regarding the position and elevation of the station was supplied by the Engineering department of the University of Saskatchewan.

No. 57, Vermilion, Alta. (1924).—The pendulum was set up in the east side of the basement of Vermilion town hall. By scaling from the plan of Vermilion the point was found to be 1,354 feet north and 1,070 feet east of the northwest corner of sec. 29, tp. 50, rge. 6, W. 4th mer. It is 14 feet 7 inches below the level of the rail in front of the C.N.R. station.

No. 58, Edmonton, Alta. (1924).—The pendulum was set up in the southwest corner of the Physics laboratory, about 54 feet north and 7 feet east of the southwest corner of the south wing of the Arts building of the University of Alberta. The point was found to be 16 feet 6 inches below the elevation of the city bench-mark in front of Alberta College and also about 6 feet 4 inches below the level of the floor of the Industrial building of the University. The equation between the levels of the city and the Geodetic Survey was obtained by comparison of their bench-marks in the Edmonton post office.

No. 59, Grande Prairie, Alta. (1924).—The pendulum was set up in the south end of the basement in Grande Prairie school, about 10 feet north and 10 feet east of the southwest corner of the building. By scaling from a plan of Grande Prairie the point

was found to be 432 feet north and 791 feet east of the southwest corner of sec. 25, tp. 71, rge. 6, W. 6th mer. It is 4 inches below the Topographical Survey bench-mark on the grounds of the Dominion Lands office.

No. 60, Kinuso, Alta. (1924).—The pendulum was set up on a concrete block about 6 feet by 3.5 feet built for a gasoline engine base in the south end of the basement of Mr. H. Walker's store. By scaling from the plan of Kinuso the point was found to be 860 feet north and 620 feet east of the northeast corner of sec. 15, tp. 73, rge. 10, W. 5th mer. It is 7 feet 6 inches below the level of the rail in front of the E.D. & B.C. railway.

No. 61, Lac la Biche, Alta. (1924).—The pendulum was set up in the south side of the billiard room in the basement of the Lac la Biche inn. By scaling from the plan of lots 42 to 79 of Lac la Biche settlement the point was found to be 1,230 feet south and 1,700 feet west of the northerly I.P.M. on the eastern boundary of the Hudson's Bay Company's reserve. It is 35 feet below the level of the rail in front of the A. & G.W. railway station.

No. 62, Waterways, Alta. (1924).—The pendulum was set on a concrete block erected in the north end of a log building, the property of the A. & G.W. railway on the northeast corner of lot 8. By scaling from the railway plan the point was found to be 141 feet south and 951 feet west of the quarter-section corner on the east boundary of sec. 31, tp. 88, rge. 8, W. 5th mer. It is 7 inches below the level of the rail in front of the A. & G.W. railway station.

No. 63, Edson, Alta. (1924).—The pendulum was set up in the south end of the room in the northeast corner of the basement of Edson school. By scaling from the plan of Edson the point was found to be 780 feet north and 4,540 feet west of the northeast corner of sec. 15, tp. 53, rge. 17, W. 5th mer. It is 5 feet 5 inches below the Geodetic Survey bench-mark in the west wall of the school.

No. 64, Jasper, Alta. (1924).—The pendulum was set up in the south side of the basement of the Administration building of Jasper Park. By measurement on the ground the point was found to be about 175 yards east of the Topographical Survey monument marked R7-191-3 on the south side of the street. It was 7 feet 7 inches below the Geodetic Survey bench-mark on the wall of the office.

No. 65, Mt. Olie, B.C. (1924).—The pendulum was set up in the southeast corner of Mr. La Virtue's store. This building is shown on the Geological Survey map (Publication No. 1997). It is the second house from the river on the south side of the road from the ferry and is shown at the first road corner from the river. The point was 1.5 feet above the level of the rail in front of the C. N. R. station.

No. 66, Princeton, B.C. (1924).—The pendulum was placed in the northerly end of the store-room in the basement of the Princeton hotel. It was 6 feet 3 inches below the level of the Geodetic Survey bench-mark on the traffic bridge.

No. 67, Phoenix, B.C. (1924).—The pendulum was set up in the northeast corner of the store-room in the north end of the office building of the Granby Mining and Smelting Company, near the western end of Old Ironsides avenue. The point was 66 feet below the level of the rail in front of the C. P. R. station.

No. 68, Nelson, B.C. (1924).—The pendulum was set up in the north end of the examination warehouse of the Customs Department, this building being a one-storey

annex on the south side of Nelson post office. The point is 75 feet south and 22 feet east of the post office corner on Vernon and Ward streets and is estimated to be 3 feet above the Geodetic Survey bench-mark which was placed in the building during the season of 1925.

No. 69, Cranbrook, B.C. (1924).—The pendulum was placed in the west end of the hallway in the south end of the basement of Cranbrook post office, 55 feet south and 40 feet west of the southwest corner of Baker street and Norbury avenue. It is 8 feet 2 inches below the level of the Geodetic Survey bench-mark on the north side of the building.

No. 70, Blairmore, Alta. (1924).—The pendulum was set up in the south end of the room in the southeast corner of the basement of the Cosmopolitan hotel. The point is 6 feet north and 25 feet east of the corner of the hotel building on Sixth and Victoria streets, and is 13 feet 8 inches below the level of the rail in front of the C. P. R. station.

No. 71, Lethbridge, Alta. (1924).—The pendulum was placed in the basement store-room next to and just west of the motor-room in the basement of the Lethbridge post office. The point is 70 feet east and 5 feet south of the northwest corner of the building on Seventh street. It is 5 feet below the Geodetic Survey bench-mark on the west side of the post office.

No. 72, Riverton, Man. (1925).—The pendulum was set up on the concrete floor of Sigurdson & Thorvaldson Company's warehouse, about 1,500 feet north and 1,620 feet west of the northeast corner of sec. 17, tp. 23, rge. 4, E. Pr. mer. The point is 13 inches above the level of the rail in front of the C. P. R. station.

No. 73, Gypsumville, Man. (1925).—The pendulum was set up in the northwest corner of the granary belonging to the Manitoba Gypsum Company. By measurement on the ground the point was found to be 480 feet north and 765 feet west of the quarter-section corner on the north boundary of sec. 23, tp. 32, rge. 9, W. Pr. mer. It is 3 feet above the level of the rail in front of the C. N. R. station.

No. 74, Manitou, Man. (1925).—The point where the pendulum was set up at Manitou is in the southeasterly corner of the furnace room of the Normal school. By scaling from the plan of Manitou it was found to be 682 feet north and 1,250 feet east of the northeast corner of sec. 24, tp. 3, rge. 9, W. Pr. mer. It is 18 feet 4 inches above the level of the rail in front of the C. P. R. station.

No. 75, Melita, Man. (1925).—The pendulum was set up in the easterly end of the basement vault of the Municipal hall. By scaling from the plan of Melita the point was found to be 1,823 feet north and 1,429 feet west of the northeast corner of sec. 36, tp. 3, rge. 27, W. Pr. mer. It is 36 feet 5 inches above the level of the rail in front of the C. P. R. station.

No. 76, Estevan, Sask. (1925).—The pendulum was set up in the north side of the basement of Estevan post office. By scaling from the plan of Estevan the point was found to be 2,089 feet south and 1,377 feet east of the quarter-section corner on the north boundary of sec. 22, tp. 2, rge. 8, W. 2nd mer. It is 6 feet 3 inches below the Geodetic Survey bench-mark in the north side of the building.

No. 77, Indian Head, Sask. (1925).—The pendulum was set up in the northwesterly corner of the basement of Indian Head fire-hall. By scaling from the plan of Indian

Head the point was found to be 3,415 feet south and 2,700 feet west of the northeast corner of sec. 24, tp. 18, rge. 13, W. 2nd mer. It is 17 feet below the level of the rail in front of the C.P.R. station.

No. 78, Moosomin, Sask. (1925).—The pendulum was set up in the northwest portion of the basement of Moosomin High school. By scaling from the plan of Moosomin the point was found to be 1,455 feet north and 843 feet east of the southwest corner of sec. 33, tp. 13, rge. 31, W. Pr. mer. It is at the same height as the rail in front of the C.P.R. station.

No. 79, Yorkton, Sask. (1925).—The pendulum was set up in the west side of the basement of Yorkton post office. By scaling from the plan of Yorkton the point was found to be 324 feet north and 669 feet east of the quarter-section corner on the south boundary of sec. 2, tp. 26, rge. 4, W. 2nd mer. It is 6 feet 7 inches below the Geodetic Survey bench-mark on the front wall of the building.

No. 80, Elbow, Sask. (1925).—The pendulum was set up in the northeasterly corner of the basement on the southerly side of Elbow school. By scaling from the plan of Elbow the point was found to be 2,225 feet south and 1,740 feet west of the northeast corner of sec. 11, tp. 25, rge. 5, W. 3rd mer. It is 3 feet 5 inches below the level of the rail in front of the C.P.R. station.

No. 81, Swift Current, Sask. (1925).—The pendulum was set up in the southwest corner of the men's cell room in the basement of the court-house at the corner of Lorne St. and 1st Ave. W. By scaling from the plan of Swift Current the point was found to be 3,340 feet north and 2,387 feet west of the southeast corner of sec. 25, tp. 15, rge. 14, W. 3rd mer. It is 4 feet 6 inches below the Geodetic Survey bench-mark on the east wall of the building.

✓ No. 82, Bassano, Alta. (1925).—The point at Bassano is on the west side of the furnace in the basement of Bassano Public school. By scaling from the plan of Bassano the pier was found to be 234 feet north and 748 feet east of the southwest corner of sec. 20, tp. 21, rge. 18, W. 4th mer. It is 4 inches above the Geodetic Survey bench-mark in the north wall of Bassano post office.

No. 83, Red Deer, Alta. (1925).—The pendulum was set up in the first room at the bottom of the landing in the south side of the basement of the armouries. The point was 25 feet north and 39 feet west of the intersection of the north boundary of 1st Ave. W. with the west boundary of 2nd St. E. and by scaling from the plan of Red Deer was found to be 2,130 feet south and 1,066 feet east of the northwest corner of sec. 16, tp. 38, rge. 27, W. 4th mer. It is 9 feet 2 inches below the level of the rail in front of the C.P.R. station.

No. 84, Coronation, Alta. (1925).—The pendulum was set up in the north side of the southwesterly room in the basement of Coronation Public school and was approximately 90 feet northerly and 150 feet easterly from the near corner of King and Norfolk streets. By scaling from the plan of Coronation the point was found to be 630 feet north and 90 feet east of the centre of sec. 13, tp. 36, rge. 11, W. 4th mer. It is 5 feet 11 inches above the level of the rail in front of the C.P.R. station.

No. 85, Paradise Mine, B.C. (1925).—The pendulum pier was a concrete block erected for the purpose in the northeasterly corner of the men's small bunk-house on the sidehill. Owing to its once having been occupied by members of a moving picture

cast the building was locally known as "Seena's Palace". It is roughly about 250 feet west of the Paradise Mine office building shown at the end of the road on Map 165A (Windermere), published by the Geological Survey. The elevation of the pier was obtained by angular measurement taken to the pier and to the peaks of Mounts Nelson and Coppercrown from two points on the rim of Paradise basin. The positions of these points with respect to the pier were determined by laying out a base line of 739 feet in the basin and by measurement of the required angles with a theodolite, which was also used to measure the angles already referred to.

No. 86, Invermere, B.C. (1925).—The pendulum was set up in the south end of the east room in the basement of Invermere hotel. The point is approximately 150 feet north and 120 feet west of the astronomical pier. The elevation of the point, which may be a few feet in error, was obtained from a contour map with 10-foot intervals supplied by the Columbia Valley Irrigation office. The equation between the levels shown on this map and those of the Geodetic Survey depends upon the elevation of lake Windermere.

No. 87, Vernon, B.C. (1925).—The pendulum was set up in the northeast corner of the main basement of Vernon post office. It is 7 feet below the Geodetic Survey bench-mark in the east wall of the building.

No. 88, Barkerville, B.C. (1925).—The pendulum pier is a concrete block erected for the purpose in a small log house belonging to Mrs. L. M. McKinnon. It is about 925 feet southwesterly along Main street and 100 feet southeasterly from the English church. The elevation of the pier was determined by aneroid readings from the bench-mark of the Geological Survey at the end near Hospital lakes of the Williams Creek base line, and also by measuring, with a theodolite, the vertical angle to Mount Greenberry.

No. 89, Tyaughton Creek, B.C. (1925).—The pendulum pier is a concrete block erected for the purpose in the first building on the north side of the road west of the Tyaughton Creek bridge and shown on the Bridge River map (Publication No. 1708 of the Geological Survey). The pier is 25 feet below the elevation of the B. C. Electric Railway bench-mark No. 11 on the south side of the road and a few yards west of the bridge across Tyaughton creek.

No. 90, Union Bay, B.C. (1925).—The pendulum was set up in the northeast corner of the basement of Nelson hotel about 15 feet south and 15 feet west of the hotel corner. It was 6 feet above high tide in front of the hotel at 4.45 p.m. on October 31, 1925.

No. 91, Cloverdale, B.C. (1925).—The pendulum was set up in the basement of Mr. M. J. Charbonneau's residence and is 4 feet below the Geodetic Survey bench-mark in Cloverdale municipal hall.

No. 92, Victoria, B.C. (1926).—The pendulum pier is the large concrete pier towards the south end of the large room on the west side of the basement of Gonzales Observatory. It is 4 feet 4 inches above the level of the Geological Survey bench-mark on Gonzales hill.

No. 93, Banfield, B.C. (1926).—The pendulum was set up in the room at the southerly end of the basement of the post office, on the front or southerly side of the building. It was found by triangulation to be 120 feet north and 1,170 feet west of

the astronomical pier. It was 26 feet 10 inches above high tide at the post office pier at about 3.15 p.m. on June 29, 1926.

No. 94, Nootka, B.C. (1926).—The pendulum was set up in the small basement store-room of Nootka lighthouse on San Rafael island. The point was 72 feet above high tide in Friendly cove at about 1.10 p.m. on July 10, 1926.

No. 95, Quatsino, B.C. (1926).—The pendulum pier is a concrete block erected for the purpose in the west end of the former home and abandoned house of Mr. Ed. Evenson. It is about 180 feet north of the post office on a knoll back from the water front. It was 37 feet above high tide at Evenson's pier at about 1.40 p.m. on July 25, 1926.

No. 96, Prince Rupert, B.C. (1926).—The pendulum was set up in the westerly end of the sample room in the northwesterly corner of the basement of Prince Rupert hotel. From information obtained at Prince Rupert City Engineer's office it was found to be, referred to the levels of the Geodetic Survey, 78 feet 6 inches above sea-level.

No. 97, Stewart, B.C. (1926).—The pendulum pier is a concrete block erected for the purpose in an abandoned house just across Bear river traffic bridge and about 150 feet south of the sharp turn in the road. The building is shown on Map No. 50A of the Geological Survey. The pier was found, by readings with the two aneroid barometers, to be 35 feet above high tide at Stewart at 1.30 p.m. on August 23, 1926.

No. 98, Masset, B.C. (1926).—The pendulum pier is a concrete block erected for the purpose in the northerly end of the basement of Mr. Wes. Singer's residence. It was 28 feet 7 inches above high tide at 8.45 a.m. at Masset dock on August 31, 1926.

No. 99, Ocean Falls, B.C. (1926).—The pendulum was set up at the entrance to the bowling alleys in the east end of the basement of the theatre. It was 55 feet above high tide at the dock at 2.11 p.m. on September 9, 1926.
